SM8029 and SM8329 are the flags shared by multiple instructions. Program flag contacts directly under each instruction. For details, refer to [Page 45 Handling general flags](#).

## Precautions

- If the ERINIT instruction is executed, an access to the SD memory card occurs and the scan time is extended.
- This instruction cannot be executed with the extended file register operation instruction simultaneously.
- When executing the following extended file register operation instruction, detect the extended file register (ER) access flag: SM9366 switching from ON to OFF, and turn on the drive contact of the extended file register operation instruction.
- The ERINIT instruction cannot be executed in the interrupt program.
- Do not turn off the power supply of the CPU module during access to the extended file register (ER).

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                     |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions perform a comparison operation between the character string data specified by (s1) and the character string data specified by (s2). (Devices are used as a normally open contact.)
- In the comparison operation, the ASCII codes of the character strings are compared one by one from the start of the strings.
- Character strings in the devices specified by (s1) and (s2) to a device that stores 00H are compared.
  - When all the character strings match, the comparison is considered as matched.

|        |                      |   |                          |
|--------|----------------------|---|--------------------------|
|        | b15 ... b8 b7 ... b0 |   | b15 ... b8 b7 ... b0     |
| (s1)   | 42H (B) : 41H (A)    | = | (s2) 42H (B) : 41H (A)   |
| (s1)+1 | 44H (D) : 43H (C)    |   | (s2)+1 44H (D) : 43H (C) |
| (s1)+2 | 00H : 45H (E)        |   | (s2)+2 00H : 45H (E)     |
|        | "ABCDE"              |   | "ABCDE"                  |

| Instruction symbol in □ | Result               |
|-------------------------|----------------------|
| \$=                     | Conductive state     |
| \$<>                    | Non-conductive state |
| \$>                     | Non-conductive state |
| \$<=                    | Conductive state     |
| \$<                     | Non-conductive state |
| \$>=                    | Conductive state     |

- When the character strings are different, the string with a large character code is considered as the large one.

|        |                      |   |                          |
|--------|----------------------|---|--------------------------|
|        | b15 ... b8 b7 ... b0 |   | b15 ... b8 b7 ... b0     |
| (s1)   | 42H (B) : 41H (A)    | > | (s2) 42H (B) : 41H (A)   |
| (s1)+1 | 44H (D) : 43H (C)    |   | (s2)+1 44H (D) : 43H (C) |
| (s1)+2 | 00H : 46H (F)        |   | (s2)+2 00H : 45H (E)     |
|        | "ABCDF"              |   | "ABCDE"                  |

| Instruction symbol in □ | Result               |
|-------------------------|----------------------|
| \$=                     | Non-conductive state |
| \$<>                    | Conductive state     |
| \$>                     | Conductive state     |
| \$<=                    | Non-conductive state |
| \$<                     | Non-conductive state |
| \$>=                    | Conductive state     |

- When the character strings are different, the magnitude relation between them is determined based on the size of the first different character code.

|        |                      |   |                          |
|--------|----------------------|---|--------------------------|
|        | b15 ... b8 b7 ... b0 |   | b15 ... b8 b7 ... b0     |
| (s1)   | 32H (2) : 31H (1)    | < | (s2) 32H (2) : 31H (1)   |
| (s1)+1 | 34H (4) : 33H (3)    |   | (s2)+1 33H (3) : 34H (4) |
| (s1)+2 | 00H : 35H (5)        |   | (s2)+2 00H : 35H (5)     |
|        | "12345"              |   | "12435"                  |

| Instruction symbol in □ | Result               |
|-------------------------|----------------------|
| \$=                     | Non-conductive state |
| \$<>                    | Conductive state     |
| \$>                     | Non-conductive state |
| \$<=                    | Conductive state     |
| \$<                     | Conductive state     |
| \$>=                    | Non-conductive state |

- When the length of the character string data differs for (s1) and (s2), the relative sizes of the character strings are determined based on the size of the first different character code.

|        |          |     |     |     |     |    |  |        |           |     |     |     |    |
|--------|----------|-----|-----|-----|-----|----|--|--------|-----------|-----|-----|-----|----|
|        | b15      | ... | b8  | b7  | ... | b0 |  | b15    | ...       | b8  | b7  | ... | b0 |
| (s1)   | 32H      | (2) | 31H | (1) |     |    |  | (s2)   | 32H       | (2) | 31H | (1) |    |
| (s1)+1 | 33H      | (3) | 34H | (4) |     |    |  | (s2)+1 | 34H       | (4) | 33H | (3) |    |
| (s1)+2 | 36H      | (6) | 35H | (5) |     |    |  | (s2)+2 | 36H       | (6) | 35H | (5) |    |
| (s1)+3 | 00H      |     | 00H |     |     |    |  | (s2)+3 | 00H       |     | 37H | (7) |    |
|        | "124356" |     |     |     |     |    |  |        | "1234567" |     |     |     |    |

| Instruction symbol in □ | Result               |
|-------------------------|----------------------|
| \$=                     | Non-conductive state |
| \$<>                    | Conductive state     |
| \$>                     | Conductive state     |
| \$<=                    | Non-conductive state |
| \$<                     | Non-conductive state |
| \$>=                    | Conductive state     |

- If the character string specified by (s1) or (s2) has more than 16383 characters, the operation result is the non-conductive state.

### Precautions

- In character string comparison operation, if the target device range does not have "00H", the values until the last number of the device are retrieved. Thus, even if the target device range does not have "00H", a comparison operation result is output when a mismatch between the acquired character strings is detected.

Ex.

- For the data specified by (s1) and (s2) as shown above, the second character is different between them. Thus, the operation result is non-conductive.

### Operation error

There is no operation error.

# Concatenating character strings

## \$(P) [For 2 operands]

FX5S

FX5UJ

FX5U

FX5UC

These instructions concatenate the character string data stored in the device specified by (s) and later to the end of the character string data stored in the device specified by (d) and later, and store the concatenated string in the device specified by (d) and later.

| Ladder diagram                                       | Structured text                                     |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions concatenate the character string data stored in the device specified by (s2) and later to the end of the character string data stored in the device specified by (s1) and later, and store the concatenated string in the device specified by (d) and later.
- Character strings in the devices specified by (s1) and (s2) up to a device that stores 00H are concatenated.

- When character strings are concatenated, 00H indicating an end of the character string specified by (s1) is ignored and the character string specified by (s2) is concatenated to the last character of (s1).
- After two character strings are connected, "00H" is automatically added at the end. When the number of characters after the concatenation is odd, 00H is stored in the upper byte of the device storing the last character. When the number is even, 0000H is stored in the device after the last character.

## Precautions

- For direct specification, up to 255 characters can be specified (input). When word devices are specified in (s1) or (s2), this restriction (up to 32 characters) is not applicable.
- When the values in both (s1) and (s2) start from "00H" (that is, when the number of characters is "0"), "0000H" is stored in (d).

## Operation error

<sup>\*1</sup> T, ST, and C cannot be used.

### Processing details

- These instructions transfer the character string data specified by (s) to the device specified by (d) and later. A character string enclosed with double quotation marks and specified by (s) or stored in the devices from the device specified by (s) to the device storing 00H is transferred in a batch.

- Even though the device range of the data to be transferred (s) to (s)+n and the device range for storing the transferred data (d) to (d)+n overlap, the processing is performed normally. For example, when a character string stored in D10 to D13 is transferred to D11 to D14, the transfer is executed as shown below:

(1): It is the same as the character string before transfer.

- When "00H" is stored in the lower byte of (s)+n, "00H" is stored to both the upper byte and lower byte of (d)+n.

(1): The high-order byte is not transferred.

(2): It is the same as the character string before transfer.

(3): "00H" is automatically stored in the high-order byte.

### Program example

In the program example shown below, character string data stored in D10 to D12 is transferred to D20 through D22 when X0 is set to ON.

### Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|

| (s)     | —                           | ○                         | —     | — | ○           | —  | ○                      | —        | — | ○  | —      |
| (d)     | —                           | ○                         | —     | — | ○           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions transfer the Unicode character string data in the device specified by (s) to the device number specified by (d) and later. The Unicode character strings specified by (s) or the Unicode character strings from the device number specified by (s) to the device number containing 0000H are transferred all at once.

- Even when the device range ((s) to (s)+n)) in which the Unicode character string data to be transferred and the device range ((d) to (d)+n) for storing the transferred data are overlapping, the processing is performed normally. For example, the character strings stored in the devices specified by D10 to D13 are transferred to the devices specified by D11 to D14 as shown below.

A: Same as before transfer

## Precautions

- The character code of the Unicode string data specified in (s) is not judged. Even if a string other than the Unicode string has been specified in (s), the word data up to 0000H are transferred to (d).
- When the data length of the Unicode string specified in (s) is 0, only the one character (one word) of termination NULL is written to (d)+0.

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions convert 16-bit binary data specified by (s) into decimal ASCII codes, and store the converted data in the device specified by (d) and later.
- The format of the decimal ASCII data to be stored in (d) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 <sup>*1</sup> | Storage format of (d)                                              | Reference                                                                       |
|-------------------------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| OFF                           | Data is stored in a fixed number of digits (a sign + 5 digits).    | Page 602 Operation of when SM705 (Number of conversion digits selection) is off |
| ON                            | Each digit is stored left-justified depending on the value of (s). | Page 602 Operation of when SM705 (Number of conversion digits selection) is on  |

\*1 For the firmware version of the CPU module supporting SM705, refer to the following.

 MELSEC iQ-F FX5 User's Manual (Application)

A CPU module which does not support SM705 operates in the same way as SM705 is off even if it is turned on.

## Operation overview

The following figure shows the operations when SM705 (Number of conversion digits selection) is off and on.

### Ex.

When the BINDA(P) instruction is executed with the numeric value "-12" stored in (s)

- When SM705 is off, the number of digits is fixed. The first character is a sign and it is 2DH(-) in the above example. (If (s) is 0 or positive, the first character is 20H (space).) The numeric part is right-justified. When the length of the numeric part is less than 5 digits, the ASCII code 20H (space) is stored for the ASCII code of the upper digit(s).
- When SM705 is on, data is left-justified. When the length of the numeric part is less than 5 digits, 00H is stored in the end.

## ■Operation of when SM705 (Number of conversion digits selection) is off

Decimal ASCII data is stored in a fixed number of digits in (d) to (d)+2.

- The following shows the operation result to be stored in (d).
  - As sign data, "20H" is stored if the binary data is positive, and "2DH" is stored if the data is negative.
  - "20H" is stored for "0" on the left side of the valid digits (zero suppression). For "00325", 20H is stored for "00", and the number of digits is 3 based on "325".
  - In the device specified by (d)+3, 0 is stored when SM701 (Output characters selection) is off, and the original data remains when SM701 is on.

### Ex.

When -12345 is specified in (s) (when signed data is specified)

## ■Operation of when SM705 (Number of conversion digits selection) is on

Decimal ASCII data is stored right-justified in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s)                                                                                                                                    | Data of (d) to (d)+2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Value of (s) | Data of (d) to (d)+2            |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |     |  |                       |  |  |                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |  |     |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |     |  |  |  |  |

ASCII 10<sup>4</sup>: ASCII code for the ten-thousands place

ASCII 10<sup>3</sup>: ASCII code for the thousands place

ASCII 10<sup>2</sup>: ASCII code for the hundreds place

ASCII 10<sup>1</sup>: ASCII code for the tens place

ASCII 10<sup>0</sup>: ASCII code for the ones place

- When the number of operation digits is less than the maximum number of digits (sign + 5 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of operation digits is equal to the maximum number of digits (a sign + 5 digits), 00H is stored in (d)+3 when SM701 is off. (d)+3 remains unchanged if SM701 is on.

## Precautions

- The number of occupied points of (d) is 3 when SM701 is on, and 4 when SM701 is off.
- When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the BINDA(P)(\_U) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

### Ex.

Executing the BINDA(P) instruction when (s) is "-12345" and then executing another BINDA(P) instruction when (s) is "-67"

- (1) "-12345" is converted into a string.
- (2) "-67" is converted into a string.
- (3) A part of the previous conversion result remains in (d)+2.

To avoid this, create a program to clear the entire data storage areas (d)+0 to (d)+2 before executing the BINDA(P)(\_U) instruction.

- (4) "-12345" is converted into a string.
- (5) (d)+0 to (d)+2 are cleared.
- (6) "-67" is converted into a string.

## Program example

In the program below, the value of 16-bit binary data D1000 is converted into decimal ASCII codes when X0 is set to ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                         |
|----------------------------|---------------------------------------------------------------------|
| 2820H                      | The device specified by (d) exceeds the corresponding device range. |

# Converting 32-bit binary data to decimal ASCII

## DBINDA(P)(\_U)

FX5S FX5UJ FX5U FX5UC

These instructions convert 32-bit binary data specified by (s) into decimal ASCII codes, and store the converted data in the device specified by (d) and later.

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions convert 32-bit binary data specified by (s) into decimal ASCII codes, and store the converted data in the device specified by (d) and later.
- The format of the decimal ASCII data to be stored in (d) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 <sup>*1</sup> | Storage format of (d)                                              | Reference                                                                       |
|-------------------------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| OFF                           | Data is stored in a fixed number of digits (a sign + 10 digits).   | Page 607 Operation of when SM705 (Number of conversion digits selection) is off |
| ON                            | Each digit is stored left-justified depending on the value of (s). | Page 608 Operation of when SM705 (Number of conversion digits selection) is on  |

<sup>\*1</sup> For the firmware version of the CPU module supporting SM705, refer to the following.

📖 MELSEC iQ-F FX5 User's Manual (Application)

A CPU module which does not support SM705 operates in the same way as SM705 is off even if it is turned on.

### ■ Operation overview

The following figure shows the operation when SM705 (Number of conversion digits selection) is off and on.

**Ex.**

When the DBINDA(P) instruction is executed with a numeric value "-123456" stored in (s)

- When SM705 is off, the number of digits is fixed. The first character is a sign and it is 2DH(-) in the above example. (If (s) is 0 or positive, the first character is 20H (space).) The numeric part is right-justified. When the length of the numeric part is less than 10 digits, the ASCII code 20H (space) is stored for the ASCII code of the upper digit(s).
- When SM705 is on, data is left-justified. When the length of the numeric part is less than 10 digits, 00H is stored in the end.

■Operation of when SM705 (Number of conversion digits selection) is off

Decimal ASCII data is stored in a fixed number of digits in (d) to (d)+5.

- The following shows the operation result to be stored in (d).
  - As sign data, "20H" is stored if the binary data is positive, and "2DH" is stored if the data is negative.
  - "20H" is stored for "0" on the left side of the valid digits (zero suppression). For "0012034560", 20H is stored for "00", and the number of digits is 8 based on "12034560".
  - In the upper 8 bits of the device specified by (d)+5, 0 is stored when SM701 (Output characters selection) is off, and 20H is stored when SM701 is on.

Ex.

When -12345678 is specified in (s) (when signed data is specified)

## ■Operation of when SM705 (Number of conversion digits selection) is on

Decimal ASCII data is stored right-justified in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s)                                                                                                                                    | Data of (d) to (d)+5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value of (s) | Data of (d) to (d)+5            |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                |  |                       |  |  |                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |     |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |     |  |  |  |  |

- When the number of operation digits is less than the maximum number of digits (a sign + 10 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of operation digits is equal to the maximum number of digits (a sign + 10 digits), 00H is stored in the upper byte of (d)+5 if SM701 is off. 20H (space) is stored in the upper byte of (d)+5 if SM701 is on.

## Precautions

- (d) occupies six points.
- When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the DBINDA(P)(\_U) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

### Ex.

Executing the DBINDA(P) instruction when (s) is "-1234567890" and then executing another DBINDA(P) instruction when (s) is "-987654"

- (1) "-1234567890" is converted into a string.  
 (2) "-987654" is converted into a string.  
 (3) A part of the previous conversion result remains in (d)+4 and (d)+5.

To avoid this, create a program to clear the entire data storage areas (d)+0 to (d)+5 before executing the DBINDA(P)(\_U) instruction.

- (4) "-1234567890" is converted into a string.  
 (5) (d)+0 to (d)+5 are cleared.  
 (6) "-987654" is converted into a string.

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions convert the (n) characters (digits) within the hexadecimal code data specified by (s) to ASCII, and store the converted data in the device specified by (d) and later.
- The 16-bit mode and 8-bit mode options are available for the ASCII(P) instructions. For the operation in each mode, refer to the proceeding pages.

- 16-bit conversion mode (while SM8161 is OFF)

Each digit of hexadecimal data stored in the device specified by (s) and later is converted into ASCII code, and transferred to the upper 8 bits and lower 8 bits of each device specified by (d) and later. SM8161 must always be off in the 16-bit conversion mode.

In the following program, conversion is executed as follows:

Devices specified by (s) and later  
(D100)=0ABCH  
(D101)=1234H  
(D102)=5678H

(1): 16-bit mode

ASCII code

|           |           |           |
|-----------|-----------|-----------|
| "0" = 30H | "1" = 31H | "5" = 35H |
| "A" = 41H | "2" = 32H | "6" = 36H |
| "B" = 42H | "3" = 33H | "7" = 37H |
| "C" = 43H | "4" = 34H | "8" = 38H |

• 8-bit conversion mode (while SM8161 is ON)

Each digit of hexadecimal data stored in the device specified by (s) and later is converted into ASCII code, and transferred to the lower 8 bits of each device specified by (d) and later. SM8161 must always be on in the 8-bit conversion mode.

In the following program, conversion is executed as follows:

Devices specified by (s) and later  
(D100)=0ABCH  
(D101)=1234H  
(D102)=5678H

(1): 8-bit mode

When SM8161 is set to on, the 8-bit mode is selected.  
The conversion processing is executed as follows.

■ Number of specified digits (characters) and conversion result

| (n)  | K1  | K2  | K3  | K4  | K5  | K6  | K7  | K8  | K9  |

| 0                            | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 1 |
|                              |   |   |   |   |   |   |   | 4 |   |   |   | 3 |   |   |   |

|            |           |           |
|------------|-----------|-----------|
| ASCII code |           |           |
| "0" = 30H  | "1" = 31H | "5" = 35H |
| "A" = 41H  | "2" = 32H | "6" = 36H |
| "B" = 42H  | "3" = 33H | "7" = 37H |
| "C" = 43H  | "4" = 34H | "8" = 38H |

## Precautions

- When outputting data in the BCD format for a printer, for example, it is necessary to convert binary data into BCD data before executing the ASCI(P) instructions.
- Whether NULL (00H) is stored after the last character or not depends on the ON/OFF status of the output character number selector signal SM701. When SM701 is off, NULL (00H) is stored. When SM701 is on, the original data remains.
- Depending on the ON/OFF status of SM701 and SM8161, the number of devices occupied by (d) differs.

| SM701 | SM8161 | Number of devices occupied by (d) |
|-------|--------|-----------------------------------|
| ON    | ON     | Number of letters                 |
| ON    | OFF    | Number of letters ÷ 2             |
| OFF   | ON     | Number of letters ÷ 1             |
| OFF   | OFF    | (Number of letters ÷ 2) + 1       |

- When HEXA(P), CRC(P), or CCD(P) is used, the extension flag SM8161 is common to other instructions. When using an instruction described above and the ASCI(P) instructions in the same program, make sure to set SM8161 to ON or OFF just before each instruction so that SM8161 does not apply to another instruction.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                |
|----------------------------|----------------------------------------------------------------------------|
| 2820H                      | The device specified by (s) or (d) exceeds the corresponding device range. |
| 3405H                      | The value specified by (s) is other than any of 1 to 32767.                |

# Converting 16-bit binary data to character string

## STR(P)(\_U)

FX5S    FX5UJ    FX5U    FX5UC

These instructions add a decimal point to the 16-bit binary data in the device specified by (s2) at the location specified by (s1), convert the data to character string data, and store the converted data in the device areas specified by (d) and later.

## Processing details

- These instructions add a decimal point to the 16-bit binary data in the device specified by (s2) at the location specified by (s1), convert the data to character string data, and store the converted data in the device areas specified by (d) and later.

- (1): Total number of digits  
 (2): Number of digits of decimal part  
 (3): Sign  
 (4): "0000H" is automatically stored at the end of the character string.  
 (5): For specifying number of all digits

- The total number of digits that can be specified by (s1) is 2 to 8.
- The number of digits in the decimal part that can be specified by (s1)+1 is 0 to 5. Note that the number of digits in the decimal part must be smaller than or equal to the total number of digits minus 3.
- The converted character string data are stored in the device areas specified by (d) and later as shown below.
  - As sign data, "20H" (space) is stored if the 16-bit binary data is positive, and "2DH" (-) is stored if the data is negative.
  - If the number of digits in the decimal part is set to other than 0, "2EH" (.) is automatically stored at the position before the specified number of digits. If the number of digits in the decimal part is 0, "2EH" (.) is not stored.

- (1): Number of digits of decimal part  
 (2): Added automatically

- If the specified number of digits in the decimal part is greater than the number of digits of the 16-bit binary data, 0(s) is automatically added and the data is regarded as "0.□□□□".

- (1): Added automatically

- If the total number of digits excluding the sign and the decimal point is greater than the number of digits of the 16-bit binary data, "20H" (space) is stored between the sign and the numeric value. If the number of digits of the 16-bit binary data is greater, an error occurs.

- (1): "20H (SP)" is stored.

- The value "00H" is automatically stored at the end of the converted character string.
- When the number of all digits is even, "0000H" is stored in the device after the last character. When the number of all digits is odd, "00H" is stored in the upper byte (8 bits) of the device storing the final character.

## Program example

In the program below, the 16-bit binary data stored in D10 is converted into a character string in accordance with the digit specification by D0 and D1 when X0 is set to ON, and then stored in D20 to D23.

## Operation error

## Processing details

- These instructions add a decimal point to the 32-bit binary data in the device specified by (s2) at the location specified by (s1), convert the data to character string data, and store the converted data in the device areas specified by (d) and later.

Ex.

When -654.321 is specified in (s2)

- (1): Total number of digits
- (2): Number of digits of decimal part
- (3): Sign
- (4): "00H" is automatically stored at the end of the character string.
- (5): For specifying number of all digits

- The total number of digits that can be specified by (s1) is 2 to 13.
- The number of digits in the decimal part that can be specified by (s1)+1 is 0 to 10. Note that the number of digits in the decimal part must be smaller than or equal to the total number of digits minus 3.
- The converted character string data are stored in the device areas specified by (d) and later as shown below.
  - As sign data, "20H" (space) is stored if the 32-bit binary data is positive, and "2DH" (-) is stored if the data is negative.
  - If the number of digits in the decimal part is set to other than 0, "2EH" (.) is automatically stored at the position before the specified number of digits. If the number of digits in the decimal part is 0, "2EH" (.) is not stored.

- If the total number of digits excluding the sign and the decimal point is greater than the number of digits of the 32-bit binary data, "20H" (space) is stored between the sign and the numeric value. If the number of digits of the 32-bit binary data is greater, an error occurs.

(1): "20H (SP)" is stored.

- The value "00H" is automatically stored at the end of the converted character string.
- When the number of all digits is even, "0000H" is stored in the device after the last character. When the number of all digits is odd, "00H" is stored in the upper byte (8 bits) of the device storing the final character.

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions convert the single-precision real number data stored in the device specified by (s1) into a character string according to the display specification stored in the device specified by (s2) and later, and store the string in the device specified by (d) and later. A real number can be directly specified as (s1).
- The data after conversion varies depending on the display specification stored in (s2).

- (1): 0: Decimal part format, 1: Exponent format  
 (2): Total number of digits  
 (3): Number of digits of decimal part  
 (4): 2 to 24 can be set.

### ■Decimal point format

- When 0 is specified in (s2), the decimal point format is applied.

- (1): Decimal point format  
 (2): Total number of digits  
 (3): Number of digits of decimal part  
 (4): Sign  
 (5): Single-precision real number  
 (6): "0000H" is automatically stored at the end of the character string.

- When the number of decimal part digits is 0, the number of digits that can be specified by (s2)+1 is "the number of digits (24 at a maximum)  $\geq 2$ ". For other than 0, the number of digits that can be specified by (s2)+1 is "the number of digits (24 at a maximum)  $\geq$  (the number of decimal point digits + 3)".
- The number of digits in the decimal part that can be specified by (s2)+2 is 0 to 7. Note that the number of digits in the decimal part must be smaller than the total number of digits minus 3.
- For example, when the total number of digits is "8", the number of digits of the decimal part is "3", and "-1.23456" is specified, data is stored in (d) and later as shown below:

- (1): Total number of digits  
(2): Number of digits of decimal part  
(3): Sign  
(4): Single-precision real number  
(5): "0000H" is automatically stored at the end of the character string.

- The converted character string data are stored in the device areas specified by (d) and later as shown below.
  - As sign data, "20H" (space) is stored if the single-precision real number is positive, and "2DH" (-) is stored if the data is negative.
  - If the decimal part of the single-precision real number data cannot be accommodated in the number of digits of the decimal part, lower digits of the decimal part are rounded off.

- (1): Total number of digits (2): Number of digits of decimal part (3): These digits are rounded off.

- If the number of digits in the decimal part is set to other than 0, "2EH" (.) is automatically stored at the position before the specified number of digits. If the number of digits in the decimal part is 0, "2EH" (.) is not stored.

- (1): Total number of digits  
(2): Number of digits of decimal part  
(3): Added automatically

- When the total number of digits subtracted by the digits for sign, decimal point, and decimal part is larger than the integer part of the single-precision real number data, "20H (space)" is stored between the sign and the integer part.

- (1): Total number of digits  
(2): Number of digits of decimal part  
(3): "20H (SP)" is stored.

- The value "00H" is automatically stored at the end of the converted character string.

## ■Exponent format

- When 1 is specified in (s2), the exponent format is applied.

- (1): Exponent format  
 (2): Total number of digits  
 (3): Number of digits of decimal part  
 (4): Single-precision real number  
 (5): Sign (integer part)  
 (6): Sign (exponent part)  
 (7): Added automatically  
 (8): "0000H" is automatically stored at the end of the character string.

- When the number of decimal part digits is 0, the number of digits that can be specified by (s2)+1 is "the number of digits (24 at a maximum)  $\geq 6$ ". For other than 0, the number of digits that can be specified by (s2)+1 is "the number of digits (24 at a maximum)  $> (\text{the number of decimal point digits} + 7)$ ".
- The number of digits in the decimal part that can be specified by (s2)+2 is 0 to 7. Note that the number of digits in the decimal part must be equal to or smaller than the total number of digits minus 7.
- For example, when the total number of digits is "12", the number of digits of the decimal part is "4", and "-12.34567" is specified, data is stored in (d) and later as shown below:

- (1): Total number of digits  
 (2): Number of digits of decimal part  
 (3): Fixed to 2 digit  
 (4): Sign (integer part)  
 (5): Sign (exponent part)  
 (6): Single-precision real number  
 (7): "0000H" is automatically stored at the end of the character string.

- The converted character string data are stored in the device areas specified by (d) and later as shown below.
  - As sign data of the integral part, "20H" (space) is stored if the single-precision real number is positive, and "2DH" (-) is stored if the data is negative.
  - The integer part is fixed to 1 digit. "20H (space)" is stored between the integer part and the sign.

- (1): Total number of digits
- (2): Fixed to 1 digit
- (3): "20H (SP)" is stored.

- If the decimal part of the single-precision real number data cannot be accommodated in the number of digits of the decimal part, lower digits of the decimal part are rounded.

- (1): Total number of digits  
(2): Number of digits of decimal part  
(3): Added automatically

- For the sign of the exponent part, "2BH (+)" is stored when the exponent is positive, and "2DH (-)" is stored when the exponent is negative.
- The exponent part is fixed to 2 digits. When the exponent part is 1 digit, "30H (0)" is stored after the sign of the exponent part.

## Program example

In the program example shown below, the contents (single-precision real number data) of R0 and R1 are converted according to the contents specified by R10 to R12, and then stored to D0 and later when X0 turns ON.

In the program shown below, the contents (single-precision real number data) of R0 and R1 are converted according to the contents specified by R10 to R12, and then stored to D10 and later when X0 turns ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Processing details

- These instruction convert the Unicode character string in the device specified by (s) to the shift JIS character string, and stores the converted data in the device specified by (d).
- Specify the Unicode string in (s) in little endian.

**Ex.**

A Unicode string "6587H" is specified.

- The shift JIS string in (d) is stored in big endian.

**Ex.**

A shift JIS string "95B6H" is specified with "B695H".

- When a byte order mark is not used, conversion from Unicode to shift JIS occurs as follows.

- When a byte order mark (FEFFH) is added, conversion from Unicode to shift JIS occurs as follows.

## Precautions

- If the Unicode string specified in (s) contains a character code that cannot be converted, the string to the character causing the error is written to the device No. specified in (d).
- 32-bit Unicode strings cannot be converted to shift JIS.
- If the device ranges specified in (s) and (d) overlap, the overlap may be detected in advance. The operation in each case of overlap of the device ranges is shown below.

[When the overlap is detected in advance]

If the overlap of the device ranges is detected in advance, the string to the overlapped point is converted and written to (d).  
Since the overlap of the device ranges in (s+3) is revealed in advance, the string in (s+0) to (s+2) is converted and written to (d+0) and (d+1).  
An overlap error (2821H) occurs.

[When the overlap cannot be detected in advance (error completion)]

Since the device ranges overlap when the string in (s+3) is converted, the next destination to store is not found.  
An overlap error (2821H) occurs.

[When the overlap cannot be detected in advance (normal completion)]

As the result of string conversion, the device ranges do not overlap, and the program terminates normally.

## Operation error

### Processing details

- These instructions convert the shift JIS character string in the device specified by (s) to a Unicode character string, and store the converted data in the device specified by (d).
- Specify the shift JIS string in (s) in big endian.

Ex.

A shift JIS string "95B6H" is specified with "B695H".

- The Unicode string in (d) is stored in little endian.

### Ex.

A Unicode string "6587H" is specified.

- The SJIS2WS(P) instruction does not add a byte order mark to the beginning of the data in the device specified by (d). To add a byte order mark, use the SJIS2WSB(P) instruction.

Page 634 SJIS2WSB(P)

- The following figure shows the operation for converting shift JIS to Unicode.

## Precautions

- When the data length of the ASCII (shift JIS) string specified in (s) is 0, only the one character (one word) of termination NULL is written to (d)+0.
- If the ASCII (shift JIS) string specified in (s) contains a character code that cannot be converted, the string to the character causing the error is written to the device No. specified in (d).
- If the device ranges specified in (s) and (d) overlap, the overlap may be detected in advance. The operation in each case of overlap of the device ranges is shown below.

[When the overlap is detected in advance]

If the overlap of the device ranges is detected in advance, the string to the overlapped point is converted and written to (d).

Since the overlap of the device ranges in (s+3) is revealed in advance, the string in (s+0) to (s+2) is converted and written to (d+0) to (d+3).

An overlap error (2821H) occurs.

[When the overlap cannot be detected in advance (error completion)]

Since the device ranges overlap when the string in (s+2) is converted, the next destination to store is not found.

An overlap error (2821H) occurs.

[When the overlap cannot be detected in advance (normal completion)]

As the result of string conversion, the device ranges do not overlap, and the program terminates normally.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                  |

| (s)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | ○  | —      |
| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions convert the shift JIS character string in the device specified by (s) to the Unicode character string, add a byte order mark to the start of the converted data, and store it in the device specified by (d).
- Specify the shift JIS string in (s) in big endian.

Ex.

A shift JIS string "95B6H" is specified with "B695H".

- The Unicode string in (d) is stored in little endian.

**Ex.**

A Unicode string "6587H" is specified.

- The following figure shows the operation for converting shift JIS to Unicode.

## Precautions

- When the data length of the ASCII (Shift JIS) string specified in (s) is 0, only the byte order mark and one character (one word) of termination NULL are written to (d)+0.
- If the ASCII (Shift JIS) string specified in (s) contains a character code that cannot be converted, the string to the character causing the error including the byte order mark is written to the device No. specified in (d).
- If the device ranges specified in (s) and (d) overlap, the overlap may be detected in advance. The operation in each case of overlap of the device ranges is shown below.

[When the overlap is detected in advance]

If the overlap of the device ranges is detected in advance, the string to the overlapped point is converted and written to (d).  
Since the overlap of the device ranges in (s+3) is revealed in advance, the string in (s+0) to (s+2) is converted and written to (d+0) to (d+3).  
An overlap error (2821H) occurs.

[When the overlap cannot be detected in advance (error completion)]

Since the device ranges overlap when the string in (s+2) is converted, the next destination to store is not found.  
An overlap error (2821H) occurs.

[When the overlap cannot be detected in advance (normal completion)]

As the result of string conversion, the device ranges do not overlap, and the program terminates normally.

## Operation error

| ENO     | Execution result                                                  | —     | Bit                  | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○*1                       | —     | — | —           | —  | ○                      | —        | — | ○  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions detect the length of the character string specified by (s), and store the length in the device specified by (d) and later.
- These instructions handle data stored in the device specified by (s) to the device storing 00H as a character string.

### Ex.

When "ABCDEFGH" is stored in (s) and later

## Precautions

The LEN(P) instructions can handle character codes other than ASCII codes, but the character string length is handled in byte units (8 bits). Accordingly, in the case of character codes in which 2 bytes express 1 character such as shift JIS codes, the length of 1 character is detected as "2".

## Program example

In the program example shown below, the length of a character string stored in D0 and later is output in 4-digit BCD to Y40 to Y57 when X0 turns ON.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------|
| 2820H                   | In the corresponding device range of the device specified by (s) and later, "00H" does not exist. |
| 3405H                   | The character string specified by (s) has more than 16383 characters.                             |

# Extracting character string data from the right

## RIGHT(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions extract "n" characters of the character string data stored in the device specified by (s) and later from the right end (from the end), and store the extracted characters in the device specified by (d) and later.

| Ladder diagram       | Structured text <sup>*1</sup> |

|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○ <sup>*1</sup>           | —     | — | —           | —  | ○                      | —        | — | ○  | —      |
| (d)     | —                           | ○ <sup>*1</sup>           | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

<sup>\*1</sup> T, ST, and C cannot be used.

## Processing details

- These instructions extract "n" characters of the character string data stored in the device specified by (s) and later from the right end (from the end), and store the extracted characters in the device specified by (d) and later.

- A character string stored in (s) indicates data stored in devices from the specified device until "00H" is first detected in units of 1 byte.

### Ex.

When 5 is specified in (n)

(1): ASCII code for 5th character

- A NULL code (00H), which indicates an end of a character string, is automatically added at the end of the character string data.
- When the number of extracted characters is odd, "00H" is stored in the upper byte of a device storing the last character. When the number of extracted characters is even, "0000H" is stored in the device after the last character.
- When the number of characters specified by (n) is 0, a NULL code (00H) is stored in (d).

## Precautions

When handling character codes other than ASCII codes, note the following points:

- The number of characters is handled in byte units (8 bits). Accordingly, in the case of character codes in which 2 bytes express 1 character such as shift JIS codes, 1 character is detected as "2".
- When extracting characters from a character string including character codes in which 2 bytes express 1 character such as shift JIS codes, consider the number of characters to be extracted in units of character codes for 1 character. Note that the expected character code is not retrieved if only 1 byte is extracted out of a 2-byte character code.

## Program example

In the program example shown below, 4 characters are extracted from the right end of the character string data stored in R0 and later, and stored to D0 and later when X0 turns ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                        |

<sup>\*1</sup> T, ST, and C cannot be used.

## Processing details

- These instructions extract "n" characters of the character string data stored in the device specified by (s) and later from the left end (from the start), and store the extracted characters in the device specified by (d) and later.

- A character string stored in (s) indicates data stored in devices from the specified device until "00H" is first detected in units of 1 byte.

### Ex.

When 7 is specified in (n)

(1): ASCII code for 7th character

- A NULL code (00H), which indicates an end of a character string, is automatically added at the end of the character string data.
- When the number of extracted characters is odd, "00H" is stored in the upper byte of a device storing the last character. When the number of extracted characters is even, "0000H" is stored in the device after the last character.
- When the number of characters specified by (n) is 0, a NULL code (00H) is stored in (d).

## Precautions

When handling character codes other than ASCII codes, note the following points:

- The number of characters is handled in byte units (8 bits). Accordingly, in the case of character codes in which 2 bytes express 1 character such as shift JIS codes, 1 character is detected as "2".
- When extracting characters from a character string including character codes in which 2 bytes express 1 character such as shift JIS codes, consider the number of characters to be extracted in units of character codes for 1 character. Note that the expected character code is not retrieved if only 1 byte is extracted out of a 2-byte character code.

## Program example

In the program example shown below, the number of characters which is equivalent to the number stored in X10 are extracted from the left end of the character string data stored in D100 and later, and stored to R10 and later when X10 turns ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------|

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions extract the number of characters specified by (s2)+1 of the character string data stored in the device specified by (s1) and later from the position specified by (s2), and store the extracted characters in the device specified by (d) and later.

(1): 5th character position (s2)

(2): ASCII code for 5th character (s2)+1

- A character string stored in (s1) indicates data stored in devices from the specified device until "00H" is first detected in units of byte.
- A NULL code (00H), which indicates an end of a character string, is automatically added at the end of the character string data.
- When the number of extracted characters "(s2)+1" is odd, "00H" is stored in the upper byte of a device storing the last character. When the number of extracted characters "(s2)+1" is even, "0000H" is stored in the device after the last character.
- If the number of characters specified by (s2)+1 is 0, no processing is performed.
- When (s2)+1 (the number of characters to be extracted) is "-1", the entire character string stored in (s1) and later is stored to (d) and later.

(1): 5th character position (s2)

## Precautions

When handling character codes other than ASCII codes, note the following points:

- The number of characters is handled in byte units (8 bits). Accordingly, in the case of character codes in which 2 bytes express 1 character such as shift JIS codes, 1 character is detected as "2".
- When extracting characters from a character string including character codes in which 2 bytes express 1 character such as shift JIS codes, consider the number of characters to be extracted in units of character codes for 1 character. Note that the expected character code is not retrieved if only 1 byte is extracted out of a 2-byte character code.

## Program example

In the program example shown below, four characters are extracted from the 3rd character from the left end of the character string data stored in D10 and later, and then stored to D0 and later when X0 turns ON.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                      |

## Processing details

- These instructions extract the number of characters specified by (s2)+1 from the character string data stored in the device specified by (s1) and later, and store the extracted data in the position specified by (s2) and later of the character string data stored in the device specified by (d) and later.

- A character string stored in (s1) or (d) indicates data stored in devices from the specified device until "00H" is first detected in units of 1 byte.
- A NULL code (00H), which indicates an end of a character string, is automatically added at the end of the character string data.
- If the number of characters specified by (s2)+1 is 0, no processing is performed.
- When the number of characters specified by (s2)+1 exceeds the last character of the character string specified by (d), data is stored up to the last character of (d).

- When (s2)+1 (the number of characters to be extracted) is "-1", the entire character string stored in (s1) and later is stored to (d) and later.

## Precautions

When handling character codes other than ASCII codes, note the following points:

- The number of characters is handled in byte units (8 bits). Accordingly, in the case of character codes in which 2 bytes express 1 character such as shift JIS codes, 1 character is detected as "2".
- When extracting characters from a character string including character codes in which 2 bytes express 1 character such as shift JIS codes, consider the number of characters to be extracted in units of character codes for 1 character. Note that the expected character code is not retrieved if only 1 byte is extracted out of a 2-byte character code.

## Program example

In the program example shown below, 4 characters are extracted from the character string data stored in D0 and later, and stored to the 3rd character (from the left end) and later for the character string data stored in D100 and later when X10 turns ON.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                  |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions search the character string data stored in the device specified by (s2) and later starting from the (s3)th character from the left, for the character string data stored in the device specified by (s1) and later and store the search result in the device specified by (d). The search result stores the position where the first detected character is located from the start character in the character string data stored in (s2).

- (1): Search start position (s3): 3rd character  
 (2): Fifth character from the head character

- If no matched character string data is found, 0 is stored in (d).
- When the search start position "s3" is a negative number or "0", search processing is not executed.
- A character string can be directly specified in the character string (s1).

- (1): Search start position (s3): 3rd character  
 (2): Fifth character from the head character

## Program example

In the program shown below, the character string stored in D0 and later is searched from the 5th character of the character string "CI2312CIM" stored in R0 and later when X0 is set to ON. The search results are stored in D100.

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions insert the character string specified by (s1) at the (s2)th character from the start of the character string specified by (d).

- When the number of characters after insertion, (s1)+(d), is even, a NULL code (00H) is stored in the device (1 word) after the last device storing the character string.
- When the number of characters after insertion, (s1)+(d), is odd, a NULL code (00H) is stored in the last device (upper 8 bits) of the character string.
- If the number of characters exceeding (d) by one character is specified in (s2), the character string in (s1) is added to the end of the character string in (d).

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions delete (n) characters starting from the (s)th character (deletion start position) from the start of the character string data specified by (d).

- When the number of characters after deletion, (d), is even, a NULL code (00H) is stored in the device after the last device storing the character string.
- When the number of characters after deletion, (d), is odd, a NULL code (00H) is stored in the last device (upper 8 bits) of the character string.
- The character string after the deleted character string is shifted by (n) characters, a NULL code (00H) is stored in vacant devices.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------|
| 2820H                   | No NULL code (00H) exists in the corresponding device range of the device specified by (d) and later.         |
| 3405H                   | The character string specified by (d) has more than 16383 characters.                                         |
|                         | (s) is not within the range ( $1 \leq (s) \leq 16383$ )                                                       |
|                         | The value specified by (s) exceeds the number of characters of the character string (d).                      |
|                         | The value specified by (n) exceeds the number of characters from (s) to the last of the character string (d). |

## 8.10 Real Number Instruction

### Comparing single-precision real numbers

LDE□, ANDE□, ORE□

FX5S

FX5UJ

FX5U

FX5UC

These instructions perform a comparison operation between the single-precision real number in the device specified by (s1) and the single-precision real number in the device specified by (s2). (Devices are used as a normally open contact.)

| Ladder diagram                                                        | Structured text <sup>*1</sup>                                                                                                    |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <p>( "=", "&lt;&gt;", "&gt;", "&lt;=", "&lt;", "&gt;=" enters □.)</p> | <pre> ENO:=LDE_□(EN,s1,s2); ENO:=ANDE_□(EN,s1,s2); ENO:=ORE_□(EN,s1,s2); ("EQ", "NE", "GT", "LE", "LT", "GE" enters □.)*2 </pre> |

FBD/LD

\*1 Supported by engineering tool version "1.035M" and later.

\*2 EQ is =, NE is <>, GT is >, LE is <=, LT is <, and GE is >=.

#### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                                   | Range                            | Data type                    | Data type (label) |

| (s2)    | —                           | ○                         | ○     | — | ○           | —  | ○                      | —        | ○ | —  | —      |

## Processing details

- These instructions perform a comparison operation between the single-precision real number in the device specified by (s1) and the single-precision real number in the device specified by (s2). (Devices are used as a normally open contact.)
- The following table lists the comparison operation results of each instruction.

| Instruction symbol | Condition      | Result           | Instruction symbol | Condition      | Result               |
|--------------------|----------------|------------------|--------------------|----------------|----------------------|
| E=                 | $(s1)=(s2)$    | Conductive state | E=                 | $(s1)\neq(s2)$ | Non-conductive state |
| E<>                | $(s1)\neq(s2)$ |                  | E<>                | $(s1)=(s2)$    |                      |
| E>                 | $(s1)>(s2)$    |                  | E>                 | $(s1)\leq(s2)$ |                      |
| E<=                | $(s1)\leq(s2)$ |                  | E<=                | $(s1)>(s2)$    |                      |
| E<                 | $(s1)<(s2)$    |                  | E<                 | $(s1)\geq(s2)$ |                      |
| E>=                | $(s1)\geq(s2)$ |                  | E>=                | $(s1)<(s2)$    |                      |

- When an input value is set from the engineering tool, a rounding error may occur.

## Operation error

There is no operation error.

When the E= instruction is used, note that values in the devices may not be equal.

(1): Values in the devices may not be equal.

# Single-precision real number comparison

## DECMP(P)

FX5S    FX5UJ    FX5U    FX5UC

These instructions compare two data values (single-precision real number), and output the result (larger, same or smaller) to three consecutive bit devices.

| Ladder diagram | Structured text                                     |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions compare the comparison value (s1) with the comparison source (s2) as floating point data, and one of the bits among (d), (d)+1, and (d)+2 turns on according to the result (smaller, same or larger).

(1): Even if the command input X0 turns off before the DECMP instruction is fully executed, (d) to (d)+2 hold the status.

- When the constant (K or H) is specified the device specified by (s1) and (s2), these instructions convert the binary value into single-precision real number automatically.

## Precautions

- Three devices ((d), (d)+1, and (d)+2) specified by (d) are occupied. Note that these devices are not used for any other purpose.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------|
| 2820H                      | The device range specified by (d) exceeds the corresponding device range.               |
| 3402H                      | The specified device value is denormalized number, NaN (not a number), or $\pm\infty$ . |

# Single-precision real number data band comparison

## DEZCP(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions compare the comparison range of two points, upper and lower, with the binary floating point, and output the result to three consecutive bit devices in accordance with the larger, smaller, and band.

| Ladder diagram | Structured text                                                            |

| (s3)    | —                           | ○                         | ○     | — | ○           | —  | ○                      | ○        | ○ | —  | —      |
| (d)     | ○                           | ○*1                       | —     | — | —           | —  | —                      | —        | — | —  | —      |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions compare the comparison values (s1) and (s2) with the comparison source (s3) as floating point data, and one of the bits among (d), (d)+1, and (d)+2 turns on according to the result (smaller, within the range or larger).

(1): Even if the command input X0 turns off before the DEZCP instruction is fully executed, (d) to (d)+2 hold the status.

- When the constant (K or H) is specified the device specified by (s1), (s2) and (s3), these instructions convert the binary value into single-precision real number automatically.

## Precautions

- Three devices ((d), (d)+1, and (d)+2) specified by (d) are occupied. Note that these devices are not used for any other purpose.
- The size relationship of the comparison data should be  $[(s1)+1, (s1)] \leq [(s2)+1, (s2)]$ . If the relationship is  $[(s1)+1, (s1)] > [(s2)+1, (s2)]$ , the value of  $[(s2)+1, (s2)]$  is regarded as the same as that of  $[(s1)+1, (s1)]$ , and is compared.

## Operation error

### Processing details

- These instructions convert the 32-bit signed binary data in the device specified by (s) to single-precision real number, and store the converted data in the device specified by (d).

### Operation error

There is no operation error.

# Converting 32-bit unsigned binary data to single-precision real number

## UDINT2FLT(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions convert the 32-bit unsigned binary data in the device specified by (s) to single-precision real number, and store the converted data in the device specified by (d).

Ladder diagram

Structured text<sup>\*1</sup>

ENO:=UDINT2FLT(EN,s,d);  
ENO:=UDINT2FLTP(EN,s,d);

FBD/LD

\*1 Supported by engineering tool version "1.035M" and later.

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions convert the character strings in the device areas specified by (s) and later to single-precision real number, and store the converted data in the device specified by (d).
- A specified character string may be in the decimal point format or exponent format. A character string in either format can be converted into single-precision real number.

(1): Indicates the end of the character string.

(2): Single-precision real number

- A character string can consist of up to 24 characters. 20H (space) and 30H (0) in a character string are counted as one character each.

## Decimal point format

- When the character string specified by (s) is decimal point format, the operation is executed as follows.

(1): Single-precision real number

- With regard to character string, six digits excluding the sign, decimal point and exponent part are valid, and the 7th and later digits are discarded during conversion.

(2): Single-precision real number

- When 2BH (+) is specified as the sign in the floating point format or when the sign is omitted, a character string is converted into a positive value. It is handled as negative value during conversion when the sign is set to 2DH (-).
- When 20H (space) or 30H (0) exists between numbers except the first 0 in a character string specified by (s), 20H or 30H is ignored during conversion.

(2): Single-precision real number

## Exponent format

- When the character string specified by (s) is in exponent format, the operation is executed as follows.

(1): Single-precision real number

- With regard to character string, six digits excluding the sign, decimal point and exponent part are valid, and the 7th and later digits are discarded during conversion.

(1): These values are discarded.

(2): Single-precision real number

- String data in the exponent format is handled as positive value during conversion when the sign of the exponent part is set to 2BH (+) or when the sign is omitted. When 2DH (-) is specified as the sign, a character string is converted into a negative value.
- When 20H (space) or 30H (0) exists between numbers except the first 0 in a character string specified by (s), 20H or 30H is ignored during conversion.
- When 30H (0) exists between a number and "E" in a character string in the exponent format, 30H is ignored during conversion.

(1): Ignored

(2): Single-precision real number

## Program example

In the program example shown below, a character string stored in R0 and later is converted into single-precision real number, and stored to D0 and D1 when X0 turns ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                             |

## Precautions

In floating point operations, all data is handled in binary floating point. Because binary floating point is difficult to understand (requiring a dedicated monitoring method), it is converted into scientific notation (decimal floating point) so that monitoring can be easily executed by peripheral equipment.

## Operation error

## Processing details

- These instructions convert the decimal floating point specified by (s) to the binary floating point, and store the converted data in the device specified by (d).

- The table below shows the related devices.

| Device | Name   | Description                                                      |                                                                                                                  |
|--------|--------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|        |        | Condition                                                        | Operation                                                                                                        |
| SM700  | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM700 turns on.    |
| SM8020 | Zero   | The operation result is true "0".<br>(The mantissa part is "0"). | The zero flag SM8020 turns on.                                                                                   |
| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$          | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Program example

In the program shown below, a numeric value containing the decimal point is converted into binary floating point.

Converting "3.14" into binary floating point

$3.14 = 314 \times 10^{-2}$  (decimal floating point)

## Operation error

There is no operation error.

# Inverting the sign of single-precision real number

## ENEG(P)/DENEG(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions invert the sign of the single-precision real number specified by (d), and store the data of the device specified by (d).

The ENEG(P) instructions can also be used as DENEG(P).

| Ladder diagram                                                                    | Structured text                       |

### Processing details

- These instructions invert the sign of the single-precision real number specified by (d), and store the data in the device specified by (d).

- Use these instructions for inverting the positive and negative sign.

### Program example

In the program example shown below, the single-precision real number stored in D100 and D101 is inverted, and the negation result is stored to D100 and D101 when X0 turns ON.

## Operation error

There is no operation error.

# Transferring single-precision real number data

## EMOV(P)/DEMOV(P)

**FX5S**   **FX5UJ**   **FX5U**   **FX5UC**

These instructions transfer the single-precision real number data stored in the device specified by (s) to the device specified by (d).

The EMOV(P) instructions can also be used as DEMOV(P).

## Processing details

- These instructions transfer the single-precision real number data stored in the device specified by (s) to the device specified by (d).

## Program example

In the program example shown below, a single-precision real number stored in D11 and D10 is transferred to D1 and D0 when X7 turns ON.

In the program shown below, a single-precision real number "-1.23" is transferred to D11 and D10 when X7 turns ON.

## Operation error

There is no operation error.

# Calculating the sine of single-precision real number

## SIN(P)/DSIN(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions calculate the sine of the angle specified by (s), and store the operation result in the device specified by (d). The SIN(P) instructions can also be used as DSIN(P).

| Ladder diagram                                                                    | Structured text <sup>*1</sup> |
|-----------------------------------------------------------------------------------|-------------------------------|
|  | ENO:=SINP(EN,s,d);            |
| FBD/LD <sup>*1</sup>                                                              |                               |
|  |                               |

<sup>\*1</sup> The SIN instruction is not supported by the ST language and the FBD/LD language. Use SIN of the standard function.

| SM8020 | Zero   | The operation result is true "0".<br>(The mantissa part is "0"). | The zero flag SM8020 turns on.                                                                                   |
| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$          | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Program example

This program designates the angle ( $45^\circ$  or  $90^\circ$ ) and calculates the SIN value when X1 or X2 is set to ON.

8

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------|
| 3402H                      | The specified device value is -0, denormalized number, NaN (not a number), or $\pm\infty$ . |

### Point

For the angle $\leftrightarrow$ radian conversion, refer to the DRAD(P) and DDEG(P) instructions.

( Page 716 Converting single-precision real number angle to radian, Page 718 Converting single-precision real number radian to angle)

# Calculating the cosine of single-precision real number

## COS(P)/DCOS(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions calculate the cosine of the angle specified by (s), and store the operation result in the device specified by (d).

The COS(P) instructions can also be used as DCOS(P).

| Ladder diagram                                                                    | Structured text <sup>*1</sup> |
|-----------------------------------------------------------------------------------|-------------------------------|
|  | ENO:=COSP(EN,s,d);            |

| FBD/LD <sup>*1</sup>                                                              |
|-----------------------------------------------------------------------------------|
|  |

<sup>\*1</sup> The COS instruction is not supported by the ST language and the FBD/LD language. Use COS of the standard function.

|--------|--------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|        |        | Condition                                                        | Operation                                                                                                        |
| SM8020 | Zero   | The operation result is true "0".<br>(The mantissa part is "0"). | The zero flag SM8020 turns on.                                                                                   |
| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$          | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Precautions

When the angle specified by (s) is  $\pi/2$  radian or  $(3/2)\pi$  radian, no error occurs because an operation error occurs in a radian value.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------|
| 3402H                      | The specified device value is -0, denormalized number, NaN (not a number), or $\pm\infty$ . |

### Point

For the angle $\leftrightarrow$ radian conversion, refer to the DRAD(P) and DDEG(P) instructions.

( Page 716 Converting single-precision real number angle to radian, Page 718 Converting single-precision real number radian to angle)

# Calculating the arc sine of single-precision real number

## ASIN(P)/DASIN(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions calculate the angle from the sine of the angle specified by (s), and store the operation result in the word device specified by (d).

The ASIN(P) instructions can also be used as DASIN(P).

| Ladder diagram                                                                    | Structured text <sup>*1</sup> |
|-----------------------------------------------------------------------------------|-------------------------------|
|  | ENO:=ASINP(EN,s,d);           |
| FBD/LD <sup>*1</sup>                                                              |                               |
|  |                               |

<sup>\*1</sup> The ASIN instruction is not supported by the ST language and the FBD/LD language. Use ASIN of the standard function.

## Processing details

- These instructions calculate the angle from the sine of the angle specified by (s), and store the operation result in the device specified by (d).

- The sine value specified by (s) can be set ranging from -1.0 to 1.0.
- The angle (operation result) stored in (d) is expressed in radians (from  $(-\pi/2)$  to  $(\pi/2)$ ).
- The table below shows the related devices.

| Device | Name   | Description                                                      |                                                                                                                  |
|--------|--------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|        |        | Condition                                                        | Operation                                                                                                        |
| SM700  | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM700 turns on.    |
| SM8020 | Zero   | The operation result is true "0".<br>(The mantissa part is "0"). | The zero flag SM8020 turns on.                                                                                   |
| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$          | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Program example

In the program example shown below, the  $\text{SIN}^{-1}$  value of data (single-precision real number) stored in D0 and D1 is calculated, and the angle is output in 4-digit BCD to Y40 to Y57 when X0 turns ON.

- Operation when "0.5" is stored in D0 and D1

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------|
| 3402H                      | The specified device value is -0, denormalized number, NaN (not a number), or $\pm\infty$ . |
| 3405H                      | A value specified in (s) is outside the range from -1.0 to 1.0.                             |

---

For the radian $\leftrightarrow$ angle conversion, refer to the DRAD(P) and DDEG(P) instructions.

( Page 716 Converting single-precision real number angle to radian, Page 718 Converting single-precision real number radian to angle)

---

# Calculating the arc cosine of single-precision real number

## ACOS(P)/DACOS(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions calculate the angle from the cosine of the angle specified by (s), and store the operation result in the word device specified by (d).

The ACOS(P) instructions can also be used as DACOS(P).

| Ladder diagram                                                                    | Structured text <sup>*1</sup> |
|-----------------------------------------------------------------------------------|-------------------------------|
|  | ENO:=ACOSP(EN,s,d)            |
| FBD/LD <sup>*1</sup>                                                              |                               |
|  |                               |

<sup>\*1</sup> The ACOS instruction is not supported by the ST language and the FBD/LD language. Use ACOS of the standard function.

## Processing details

- These instructions calculate the angle from the cosine of the angle specified by (s), and store the operation result in the device specified by (d).

- The cosine value specified by (s) can be set ranging from -1.0 to 1.0
- The angle (operation result) stored in (d) is expressed in radians (0 to  $\pi$ ).
- The table below shows the related devices.

| Device | Name   | Description                                                      |                                                                                                                  |
|--------|--------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|        |        | Condition                                                        | Operation                                                                                                        |
| SM700  | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM700 turns on.    |
| SM8020 | Zero   | The operation result is true "0".<br>(The mantissa part is "0"). | The zero flag SM8020 turns on.                                                                                   |
| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$          | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Program example

In the program example shown below, the  $\text{COS}^{-1}$  value of data (single-precision real number) stored in D0 and D1 is calculated, and the angle is output in 4-digit BCD to Y40 to Y57 when X0 turns ON.

- Operation when "0.5" is stored in D0 and D1

## Operation error

| Error code (SD0/SD8067) | Description                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------|
| 3402H                   | The specified device value is -0, denormalized number, NaN (not a number), or $\pm\infty$ . |
| 3405H                   | A value specified in (s) is outside the range from -1.0 to 1.0.                             |

---

For the radian $\leftrightarrow$ angle conversion, refer to the DRAD(P) and DDEG(P) instructions.

( Page 716 Converting single-precision real number angle to radian, Page 718 Converting single-precision real number radian to angle)

# Calculating the arc tangent of single-precision real number

## ATAN(P)/DATAN(P)

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

These instructions calculate the angle from the tangent of the angle specified by (s), and store the operation result in the word device specified by (d).

The ATAN(P) instructions can also be used as DATAN(P).

| Ladder diagram                                                                    | Structured text <sup>*1</sup> |
|-----------------------------------------------------------------------------------|-------------------------------|
|  | ENO:=ATANP(EN,s,d);           |
| FBD/LD <sup>*1</sup>                                                              |                               |
|  |                               |

<sup>\*1</sup> The ATAN instruction is not supported by the ST language and the FBD/LD language. Use ATAN of the standard function.

## Processing details

- These instructions convert a unit of angle from radians specified by (s) into degrees (DEG.), and store the converted angle in the device specified by (d).

- The conversion from radians into degrees is executed as follows:

$$\text{Degrees} = \text{Radians} \times \frac{180}{\pi}$$

- The table below shows the related devices.

| Device | Name  | Description                                               |                                                                                                               |

| SM700  | Carry | The absolute value of the operation result $\geq 2^{128}$ | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM700 turns on. |

| Device | Name   | Description                                               |                                                                                                                  |
|--------|--------|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|        |        | Condition                                                 | Operation                                                                                                        |
| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$   | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$ | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Program example

In the program example shown below, the exponential operation is executed for a value set in the 2-digit BCD format in X20 to X27, and the operation result is stored in the single-precision real number format to D0 and D1 when X0 turns ON.

- Operation when "13" is specified in X20 to X27

- <sup>\*1</sup> The operation result becomes less than  $2^{128}$  when the BCD value set in X20 to X27 is "88" or less because of " $\log_e 2^{128} = 88.7$ ". If a value "89" or more is set, an operation error occurs. To prevent this operation error, when a value more than "89" is set, M0 is set to ON so that the exponential operation is not executed.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------|
| 3402H                   | The specified device value is -0, denormalized number, NaN (not a number), or $\pm\infty$ . |

### Point

- The EXP(P) instructions execute operations in natural logarithm. For obtaining a value in common logarithm, specify a common logarithm value divided by 0.4342945 in (s).

$$10^X = e^{\frac{X}{0.4342945}}$$

# Calculating the natural logarithm of single-precision real number

## LOG(P)/DLOGE(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions calculate the logarithm whose base is natural logarithm e of a value specified by (s), and store the operation result in the device specified by (d).

The LOG(P) instructions can also be used as DLOGE(P).

| Ladder diagram                                                                    | Structured text <sup>*1</sup> |
|-----------------------------------------------------------------------------------|-------------------------------|

## Processing details

- These instructions calculate the logarithm whose base is natural logarithm e of a value specified by (s), and store the operation result in the device specified by (d).

- Only a positive value can be set in (s). (The natural logarithm operation cannot be executed for a negative value).
- The table below shows the related devices.

| Device | Name  | Description                                               |                                                                                                               |
|--------|-------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
|        |       | Condition                                                 | Operation                                                                                                     |
| SM700  | Carry | The absolute value of the operation result $\geq 2^{128}$ | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM700 turns on. |

| Device | Name   | Description                                                      |                                                                                                                  |
|--------|--------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|        |        | Condition                                                        | Operation                                                                                                        |
| SM8020 | Zero   | The operation result is true "0".<br>(The mantissa part is "0"). | The zero flag SM8020 turns on.                                                                                   |
| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$          | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Program example

In the program example shown below, natural logarithm of "10" set in D50 is calculated, and stored to D30 and D31 when X0 turns ON.

## Operation error

| Error code (SD0/SD8067) | Description                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------|
| 3402H                   | The specified device value is denormalized number, NaN (not a number), or $\pm\infty$ . |
| 3405H                   | The value stored in a device specified in (s) is negative.                              |
|                         | The value stored in a device specified in (s) is 0.                                     |

# Calculating the exponentiation of single-precision real number

## POW(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions raise float (single precision) data stored in a device specified by (s1) by the single-precision real number specified by (s2), and store the operation result in a device specified by (d).

## Processing details

- These instructions raise float (single precision) data stored in a device specified by (s1) by the single-precision real number specified by (s2), and store the operation result in a device specified by (d).

- Values in the devices specified (stored) by (s1) and (s2) should be 0 or  $2^{-126} \leq |\text{specified value (stored value)}| < 2^{128}$ .
- When the operation result is -0 or underflow occurs, the operation result is regarded as 0.
- When an input value is set from the engineering tool, a rounding error may occur.

## Operation error

| SM8021 | Borrow | The absolute value of the operation result $< 2^{-126}$          | The value of (d) is the minimum value ( $2^{-126}$ ) of 32-bit real numbers and the borrow flag SM8021 turns on. |
| SM8022 | Carry  | The absolute value of the operation result $\geq 2^{128}$        | The value of (d) is the maximum value ( $2^{128}$ ) of 32-bit real numbers and the carry flag SM8022 turns on.   |

## Program example

In the program example shown below, common logarithm of "15" set in D50 is calculated, and stored to D30 and D31 when X0 turns ON.

## Operation error

| Error code (SD0/SD8067) | Description                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------|
| 3402H                   | The specified device value is denormalized number, NaN (not a number), or $\pm\infty$ . |
| 3405H                   | The value stored in a device specified in (s) is negative.                              |
|                         | The value stored in a device specified in (s) is 0.                                     |

# Searching the maximum value of single-precision real number

## EMAX(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions search for the maximum value in the (n) point(s) of single-precision real number block data in the device starting from the one specified by (s), and store the maximum value in the device areas specified by (d) and (d)+1.

These instructions also store the location of the first maximum value from (s) in the device specified by (d)+2 and the number of maximum values in the device specified by (d)+3.

| Ladder diagram                                                                    | Structured text <sup>*1</sup> |
|-----------------------------------------------------------------------------------|-------------------------------|
|  | ENO:=EMAXP(EN,s,n,d);         |

| FBD/LD <sup>*1</sup>                                                              |
|-----------------------------------------------------------------------------------|
|  |

<sup>\*1</sup> The EMAX instruction is not supported by the ST language and the FBD/LD language. Use MAX of the standard function.

## Processing details

- These instructions search for the maximum value in the (n) point(s) of single-precision real number block data in the device starting from the one specified by (s), and store the maximum value in the device areas specified by (d). These instructions also store the location of the first maximum value from (s) in the device specified by (d)+2 and the number of maximum values in the device specified by (d)+3.
- The start of the block data in the device specified by (s) is counted as 1st point when the location is counted.

(d)+1, (d): Maximum value

(d)+2: Position

(d)+3: Number of data

- The following values are stored in (d).

|       | Data type                    | Description              |
|-------|------------------------------|--------------------------|
| (d)   | Single-precision real number | Maximum value            |
| (d)+1 |                              |                          |
| (d)+2 | 16-bit data                  | Maximum value position   |
| (d)+3 | 16-bit data                  | Number of maximum values |

- When (n) is 0, the processing is not performed.

## Operation error

## Processing details

- These instructions search for the minimum value in the (n) point(s) of single-precision real number block data in the device starting from the one specified by (s), and store the minimum value in the device areas specified by (d) and (d)+1. These instructions also store the location of the first minimum value from (s) in the device specified by (d)+2 and the number of minimum values in the device specified by (d)+3.
- The start of the block data in the device specified by (s) is counted as 1st point when the location is counted.

(d)+1, (d): Minimum value

(d)+2: Position

(d)+3: Number of data

- The following values are stored in (d).

|       | Data type                    | Description              |
|-------|------------------------------|--------------------------|
| (d)   | Single-precision real number | Minimum value            |
| (d)+1 |                              |                          |
| (d)+2 | 16-bit data                  | Minimum value position   |
| (d)+3 | 16-bit data                  | Number of minimum values |

- When (n) is 0, the processing is not performed.

## Operation error

# 8.11 Random Number Instruction

## Generating random number

### RND(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions generate a pseudo-random number ranging from 0 to 32767, and store it as a random number to a device specified by (d).

| Ladder diagram                                                                    | Structured text                     |

| ENO     | Execution result                           | —     | Bit                  | BOOL              |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions generate a pseudo-random number ranging from 0 to 32767, and store it as a random number to a device specified by (d).
- In the pseudo-random number sequence, the source value of a random number is calculated every time, and this instruction calculates a pseudo-random number using the source value.

Pseudo-random number calculation equation:

(SD8311, SD8310)=(SD8311, SD8310)<sup>\*1</sup>×1103515245+12345

(d) ="([SD8311, SD8310]>>16)&<logical product>00007FFFh"

- \*1 To (SD8311, SD8310), write a non-negative value (0 to 2147483647) only once when the CPU module mode switches from STOP to RUN. (K1 is written to (SD8311, SD8310) as the initial value when the power is restored.)

## Program example

When the PLC mode switches from STOP to RUN, the time data converted into seconds and added by the value "(Year + Month) × Day" is written to SD8311 and SD8310.

In the program example shown below, a random number is stored to D100 every time X10 turns ON.

## Operation error

There is no operation error.

## 8.12 Index Register Operation Instruction

### Saving all data of the index register

#### ZPUSH(P)

**FX5S****FX5UJ****FX5U****FX5UC**

These instructions save the contents of index registers and long index registers in the devices specified by (d) and later.

| Ladder diagram                                                                    | Structured text                          |
|-----------------------------------------------------------------------------------|------------------------------------------|
|  | ENO:=ZPUSH(EN,d);<br>ENO:=ZPUSHHP(EN,d); |
| FBD/LD                                                                            |                                          |
|  |                                          |

#### Setting data

##### ■Descriptions, ranges, and data types

| Operand | Description                                                                        | Range | Data type            | Data type (label) |
|---------|------------------------------------------------------------------------------------|-------|----------------------|-------------------|
| (d)     | Head device number for saving the data of index registers and long index registers | —     | 16-bit signed binary | ANY16             |
| EN      | Execution condition                                                                | —     | Bit                  | BOOL              |
| ENO     | Execution result                                                                   | —     | Bit                  | BOOL              |

##### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |

#### Processing details

- These instructions save the contents of index registers and long index registers in the devices specified by (d) and later.
- When the contents of index registers are saved, "1" is added to (d).
- The contents of index registers and long index registers for 24 words are saved. The number of points differs for each CPU module as explained below.
  - FX5S/FX5U/FX5UC CPU module: The assigned range of index registers and long index register points is saved.
  - FX5UJ CPU module: The contents for 20 points of the index register and 2 points of the long index register are saved.
- The ZPOP(P) instructions are used to return the data. The ZPUSH(P) and ZPOP(P) instructions are used in pairs, and by using the same device in (d) a nesting structure can be adopted. (  Page 739 Returning all data of the index register)
- When a nesting structure is adopted, the areas to be used are added to (d) and later every time the ZPUSH(P) instructions are used. Check the number of index registers and long index registers by SD300 and SD302, and secure the areas for the number of instructions to be used in advance.

- The following shows the areas of (d) and later to be used.

- (1): Number of times of batch-storage  
 (2): 1st nesting (24 words for one nesting)  
 (3): 2nd nesting

## Precautions

- When a nesting structure is not adopted, clear (d) before executing the ZPUSH(P) instructions.
- When a nesting structure is adopted, clear (d) before executing the first ZPUSH(P) instructions.
- When the ZPOP(P) instructions are used to return the data of index registers, use the ZPOP(P) instructions corresponding to the ZPUSH(P) instructions that were used for saving the data.  
 ZPUSH(P) (One setting data) → ZPOP(P) (One setting data)  
 ZPUSH(P) (Two setting data) → ZPOP(P) (Two setting data)
- Secure the areas so that the save destination specified by (d) do not exceed the device range.

## Program example

In the program shown below, the contents of the index register (Z) before execution of the subroutine program are batch-stored in D0 and later when index registers are used in the subroutine program after the pointer P0.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------|
| 2820H                      | The range of points used in (d) or later exceeds the range of the target device/label area. |
| 3405H                      | (d) is negative.                                                                            |

# Returning all data of the index register

## ZPOP(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions read the data saved in the devices specified by (d) and later to index registers and long index registers.

| Ladder diagram                                                                    | Structured text                       |

## Processing details

- These instructions read the data saved in the devices specified by (d) and later to index registers and long index registers.
- When the saved contents of the index registers and long index registers are read, "1" is subtracted from (d).
- The ZPUSH(P) instructions are used to temporarily save the data. The ZPUSH(P) and ZPOP(P) instructions are used in pairs.

## Program example

For a program example, refer to  Page 736 Saving all data of the index register.

|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | —     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions save the contents of index registers and long index registers within the range specified by (s) in the devices specified by (d) and later. The type of the index register or long index register saved is stored in the end of the saved data.
- When the contents of the index registers and long index registers are saved, "1" is added to (d).
- The following shows values specified by (s) and the index register or long index register to be saved.

| (s) value | Z or LZ to be saved |
|-----------|---------------------|
| 0         | Z, LZ (whole range) |
| 1         | Z (whole range)     |
| 2         | LZ (whole range)    |

- The selected data of index register/long index register return instructions (ZPOP(P) instructions) are used to return the data. The selected data of index register/long index register save instructions (ZPUSH(P) instructions) and the selected data of index register/long index register return instructions (ZPOP(P) instructions) can be used in pairs and to adopt a nesting structure. (  Page 742 Returning the selected data of the index register and long index register)

- When a nesting structure is adopted, the areas to be used are added to (d) and later every time the selected data of index register/long index register save instructions (ZPUSH(P) instructions) are executed. Check the number of index registers and long index registers by SD300 and SD302, and secure the areas for the number of instructions to be used in advance.
- The following shows the areas of (d) and later used for the instructions (when Z0 to 13 and LZ0 to 4 are used).

## Precautions

- When a nesting structure is not adopted, clear (d) before executing the ZPUSH(P) instructions.
- When a nesting structure is adopted, clear (d) before executing the first ZPUSH(P) instructions.
- When the ZPOP(P) instructions are used to return the data of index registers, use the ZPOP(P) instructions corresponding to the ZPUSH(P) instructions that were used for saving the data.  
 ZPUSH(P) (One setting data) → ZPOP(P) (One setting data)  
 ZPUSH(P) (Two setting data) → ZPOP(P) (Two setting data)
- Do not change the values of (d)+1 and (d)+2 because they are used by the system. Do not change the values of the Z and LZ save types stored in the devices specified by (d) and later because they are used by the system.
- Secure the areas so that the save destination specified by (d) does not exceed the device range.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------|
| 2820H                      | The range of points used in (d) or later exceeds the range of the target device/label area. |
| 3405H                      | A value other than 0 to 2 is specified in (s).                                              |
|                            | When the number of index registers is 0, "1" is specified in (s).                           |
|                            | When the number of long index registers is 0, "2" is specified in (s).                      |

# Returning the selected data of the index register and long index register

## ZPOP(P)

**FX5S****FX5UJ****FX5U****FX5UC**

These instructions read the data saved in the devices specified by (d) and later to index registers and long index registers.

| Ladder diagram                                                                    | Structured text                               |

## 8.13 Data Control Instruction

### Upper and lower limit control of 16-bit binary data

#### LIMIT(P)(\_U)

**FX5S****FX5UJ****FX5U****FX5UC**

These instructions control the output value to be stored in the device specified by (d) by checking the input value (16-bit binary data) in the device specified by (s3) with the upper and lower limit values specified by (s1) and (s2).

| Ladder diagram                                                                    | Structured text*1           |                               |
|-----------------------------------------------------------------------------------|-----------------------------|-------------------------------|
|  | ENO:=LIMITP(EN,s1,s2,s3,d); | ENO:=LIMITP_U(EN,s1,s2,s3,d); |

#### FBD/LD\*1

\*1 The LIMIT and LIMIT\_U instructions are not supported by the ST language and the FBD/LD language. Use LIMIT of the standard function.

| (s2)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (s3)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions control the output value to be stored in the device specified by (d) by checking the input value (16-bit binary data) in the device specified by (s3) with the upper and lower limit values specified by (s1) and (s2). The output value is controlled as follows.

| Condition                                                          | Output value           |
|--------------------------------------------------------------------|------------------------|
| Lower limit value (s1) > Input value (s3)                          | Lower limit value (s1) |
| Upper limit value (s2) < Input value (s3)                          | Upper limit value (s2) |
| Lower limit value (s1) ≤ Input value (s3) ≤ Upper limit value (s2) | Input value (s3)       |

- To control the input value only with the upper limit, set the minimum value within the setting range in (s1).
- To control the input value only with the lower limit, set the maximum value within the setting range in (s2).

## Program example

In the program example shown below, the BCD data set in X20 to X37 is controlled by the limit values "500" to "5000", and the controlled value is output to D1 when X0 turns ON.

### Operation

- In the case of "D0 < 500", "500" is output to D1.
- In the case of "500 ≤ D0 ≤ 5000", the value of D0 is output to D1.
- In the case of "D0 > 5000", "5000" is output to D1.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------|
| 3405H                   | The lower limit value specified by (s1) is greater than the upper limit value specified by (s2). |

# Upper and lower limit control of 32-bit binary data

## DLIMIT(P)(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions control the output value to be stored in the device specified by (d) by checking the input value (32-bit binary data) in the device specified by (s3) with the upper and lower limit values specified by (s1) and (s2).

## Processing details

- These instructions control the output value to be stored in the device specified by (d) by checking the input value (32-bit binary data) in the device specified by (s3) with the upper and lower limit values specified by (s1) and (s2). The output value is controlled as follows.

| Condition                                                                                                                | Output value                       |
|--------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| Lower limit value $((s1), (s1)+1) > \text{Input value } ((s3), (s3)+1)$                                                  | Lower limit value $((s1), (s1)+1)$ |
| Upper limit value $((s2), (s2)+1) < \text{Input value } ((s3), (s3)+1)$                                                  | Upper limit value $((s2), (s2)+1)$ |
| Lower limit value $((s1), (s1)+1) \leq \text{Input value } ((s3), (s3)+1) \leq \text{Upper limit value } ((s2), (s2)+1)$ | Input value $((s3), (s3)+1)$       |

- To control the input value only with the upper limit, set the minimum value within the setting range in (s1).
- To control the input value only with the lower limit, set the maximum value within the setting range in (s2).

## Program example

In the program example shown below, the BCD data set in X20 to X57 is controlled by the limit values "10000" and "1000000", and the controlled value is output to D11 and D10 when X0 turns ON.

### Operation

- In the case of  $(D1, D0) < 10000$ , "10000" is output to (D11, D10).
- In the case of  $10000 \leq (D1, D0) \leq 1000000$ , the value of (D1, D0) is output to (D11, D10).
- In the case of  $(D1, D0) > 1000000$ , "1000000" is output to (D11, D10).

## Operation error

## Processing details

- These instructions control the output value to be stored in the device specified by (d) by checking the input value (16-bit binary data) in the device specified by (s3) with the upper and lower limit values of the dead band specified by (s1) and (s2). The output value is controlled as follows.

| Condition                                                                                            | Output value                                               |
|------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| Lower limit value of the dead band (s1) > Input value (s3)                                           | Input value (s3) - Lower limit value of the dead band (s1) |
| Upper limit value of the dead band (s2) < Input value (s3)                                           | Input value (s3) - Upper limit value of the dead band (s2) |
| Lower limit value of the dead band (s1) ≤ Input value (s3) ≤ Upper limit value of the dead band (s2) | 0                                                          |

- When the output value to be stored in the device specified by (d) is a 16-bit signed binary value and the operation result exceeds the range of -32768 to 32767, the output value is calculated as follows.

**Ex.**

When (s1) is 10 and (s3) is -32768: Output value =  $-32768 - 10 = 8000\text{H} - 000\text{AH} = 7\text{FFFH} = 32758$

- When the output value to be stored in the device specified by (d) is a 16-bit unsigned binary value and the operation result exceeds the range of 0 to 65535, the output value is calculated as follows.

**Ex.**

When (s1) is 100 and (s3) is 50: Output value =  $50 - 100 = 0032\text{H} - 0064\text{H} = \text{FFCEH} = 65486$

## Program example

In the program example shown below, the data of D0 is controlled by the dead band of the limit values "-1000" to "+1000", and the controlled value is output to D1 when X0 is set to ON.

Operation

- In the case of " $D0 < -1000$ ", " $D0 - (-1000)$ " is output to D1.
- In the case of " $-1000 \leq D0 \leq +1000$ ", "0" is output to D1.
- In the case of " $+1000 < D0$ ", " $D0 - 1000$ " is output to D1.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                      |

## Processing details

- These instructions control the output value to be stored in the device specified by (d) by checking the input value (32-bit binary data) in the device specified by (s3) with the upper and lower limit values of the dead band specified by (s1) and (s2). The output value is controlled as follows.

| Condition                                                                                                                                                                                  | Output value                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Lower limit value of the dead band $((s1), (s1)+1) > \text{Input value } ((s3), (s3)+1)$                                                                                                   | Input value $((s3), (s3)+1)$ - Lower limit value of the dead band $((s1), (s1)+1)$ |
| Upper limit value of the dead band $((s2), (s2)+1) < \text{Input value } ((s3), (s3)+1)$                                                                                                   | Input value $((s3), (s3)+1)$ - Upper limit value of the dead band $((s2), (s2)+1)$ |
| Lower limit value of the dead band $((s1), (s1)+1) \leq \text{Input value } ((s3), (s3)+1)$<br>Upper limit value of the dead band $((s2), (s2)+1) \leq \text{Input value } ((s3), (s3)+1)$ | 0                                                                                  |

- When the output value to be stored in the device specified by (d) is a 32-bit signed binary value and the operation result exceeds the range of -2147483648 to 2147483647, the output value is calculated as follows.

**Ex.**

When (s1) and (s1)+1 are 1000, and (s3) and (s3)+1 are -2147483648: Output value = -2147483648-1000 = 80000000H-000003E8H = 7FFFC18H = 2147482648

- When the output values to be stored in the devices specified by (d) and (d)+1 are 32-bit unsigned binary values and the operation result exceeds the range of 0 to 4294967295, the output value is calculated as follows.

**Ex.**

When (s1) and (s1)+1 are 100, and (s3) and (s3)+1 are 50: Output value = 50-100 = 00000032H-00000064H = FFFFFFFCEH = 4294967246

## Program example

In the program example shown below, the data of D0 and D1 is controlled by the dead band of the limit values "-10000" to "+10000", and the controlled values are output to D10 and D11 when X0 is set to ON.

### Operation

- In the case of  $(D1, D0) < -10000$ ,  $(D1, D0) - (-10000)$  is output to (D11, D10).
- In the case of  $-10000 \leq (D1, D0) \leq +10000$ , "0" is output to (D11, D10).
- In the case of  $(D1, D0) > +10000$ ,  $(D1, D0) - 10000$  is output to (D11, D10).

## Operation error

## Processing details

- These instructions add the bias value specified by (s1) or (s2) to the input value (16-bit binary data) specified by (s3), and store the operation result in the device specified by (d). The bias value is controlled as follows.

| Condition            | Output value                                |
|----------------------|---------------------------------------------|
| Input value (s3) < 0 | Input value (s3) + Negative bias value (s1) |
| Input value (s3) = 0 | 0                                           |
| Input value (s3) > 0 | Input value (s3) + Positive bias value (s2) |

- When the output value to be stored in the device specified by (d) is a 16-bit signed binary value and the operation result exceeds the range of -32768 to 32767, the output value is calculated as follows.

**Ex.**

When (s1) is -100 and (s3) is -32768: Output value =  $-32768 + (-100) = 8000\text{H} - \text{FF}9\text{CH} = 7\text{F}9\text{CH} = 32668$

- When the output value to be stored in the device specified by (d) is a 16-bit unsigned binary value and the operation result exceeds the range of 0 to 65535, the output value is calculated as follows.

**Ex.**

When (s2) is 100 and (s3) is 65535: Output value =  $65535 + 100 = \text{FFFFH} - 0064\text{H} = 0063\text{H} = 99$

- When the ZONE(P)\_U instructions are used, (s1) is regarded as dummy data and ignored.

## Program example

In the program example shown below, the data of D0 is controlled by the zone of the limit values "-1000" to "+1000", and the controlled value is output to D1 when X0 is set to ON.

Operation

- In the case of "D0 < 0", "D0 + (-1000)" is output to D1.
- In the case of "D0 = 0", "0" is output to D1.
- In the case of "0 < D0", "D0 + 1000" is output to D1.

## Operation error

There is no operation error.

## Processing details

- These instructions process the scaling conversion data (in 16-bit data units) specified by (s2) by scaling it based on the input value specified by (s1), and store the operation result in the device number specified by (d). The scaling conversion is performed based on the scaling conversion data stored in the device specified by (s2) and later.

| Setting item ("n" indicates the number of coordinate points specified by (s2).) |              | Device assignment |
|---------------------------------------------------------------------------------|--------------|-------------------|
| Number of coordinate points                                                     |              | (s2)              |
| Point 1                                                                         | X coordinate | (s2)+1            |
|                                                                                 | Y coordinate | (s2)+2            |
| Point 2                                                                         | X coordinate | (s2)+3            |
|                                                                                 | Y coordinate | (s2)+4            |
| ⋮                                                                               |              |                   |
| Point n                                                                         | X coordinate | (s2)+2n-1         |
|                                                                                 | Y coordinate | (s2)+2n           |

- If the operation result is not an integer, the number in the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in the ascending order.
- Set (s1) within the scaling conversion data range (device value of (s2)).
- If the same X coordinate is specified by multiple points, the Y coordinate value of the point whose number is the largest is output.
- Set the number of coordinate points for the scaling conversion data within the range of 1 to 65535.
- Setting example of the conversion table for scaling

In the case of the conversion characteristics for scaling shown in the figure below, set each value as shown in the following data table.

|                        | Y coordinate | (s2)+20                             | R20 | K7              |

\*1 When coordinates are specified using three points, the output value can be set to an intermediate value.

In this example, the output value (intermediate value) is specified by the Y coordinate of the point 5.

Even if the X coordinate is the same at three points or more, the value at the second point is output.

\*2 When coordinates are specified using two points, the output value is the Y coordinate at the next point.

In this example, the output value is specified by the Y coordinate of the point 9.

## Program example

In the program example shown below, the value input to D0 is processed by scaling based on the conversion table for scaling set in R0 and later, and output to D10. It is assumed that the values for the conversion table for scaling are set in R0 and later beforehand.

• Operation

• Conversion table for scaling

| Set item                    |              | Device | Setting contents |
|-----------------------------|--------------|--------|------------------|
| Number of coordinate points |              | R0     | K6               |
| Point 1                     | X coordinate | R1     | K0               |
|                             | Y coordinate | R2     | K0               |

## Processing details

- These instructions process the scaling conversion data (in 32-bit data units) specified by (s2) by scaling it based on the input value specified by (s1), and store the operation result in the device number specified by (d). The scaling conversion is performed based on the scaling conversion data stored in the device specified by (s2) and later.

| Setting item ("n" indicates the number of coordinate points specified by (s2).) |              | Device assignment    |
|---------------------------------------------------------------------------------|--------------|----------------------|
| Number of coordinate points                                                     |              | (s2)+1, (s2)         |
| Point 1                                                                         | X coordinate | (s2)+3, (s2)+2       |
|                                                                                 | Y coordinate | (s2)+5, (s2)+4       |
| Point 2                                                                         | X coordinate | (s2)+7, (s2)+6       |
|                                                                                 | Y coordinate | (s2)+9, (s2)+8       |
| ⋮                                                                               |              |                      |
| Point n                                                                         | X coordinate | (s2)+4n-1, (s2)+4n-2 |
|                                                                                 | Y coordinate | (s2)+4n+1, (s2)+4n   |

- If the operation result is not an integer, the number in the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in the ascending order.
- Set (s1) within the scaling conversion data range (device values of (s2) and (s2)+1).
- If the same X coordinate is specified by multiple points, the Y coordinate value of the point whose number is the largest is output.
- Set the number of coordinate points for the scaling conversion data within the range of 1 to 4294967295.
- Setting example of the conversion table for scaling

In the case of the conversion characteristics for scaling shown in the figure below, set each value as shown in the following data table.

|                       | Y coordinate | (s2)+41, (s2)+40                    | R41, R40 | K7              |

\*1 When coordinates are specified using three points, the output value can be set to an intermediate value.

In this example, the output value (intermediate value) is specified by the Y coordinate of the point 5.

Even if the X coordinate is the same at three points or more, the value at the second point is output.

\*2 When coordinates are specified using two points, the output value is the Y coordinate at the next point.

In this example, the output value is specified by the Y coordinate of the point 9.

## Operation error

|                                                                                 | ⋮       | ⋮                 |
|                                                                                 | Point n | (s2)+2n           |

- If the operation result is not an integer, the number in the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in the ascending order.
- Set (s1) within the scaling conversion data range (device value of (s2)).
- If the same X coordinate is specified by multiple points, the Y coordinate value of the point whose number is the largest is output.
- Set the number of coordinate points for the scaling conversion data within the range of 1 to 65535.

- Setting example of the conversion table for scaling

In the case of the conversion characteristics for scaling shown in the figure below, set each value as shown in the following data table.

| Setting item                |           | Setting device and setting contents |     |                 |
|-----------------------------|-----------|-------------------------------------|-----|-----------------|
|                             |           | When R0 is specified in (s2)        |     | Setting details |
| Number of coordinate points |           | (s2)                                | R0  | K10             |
| X coordinate                | Point 1   | (s2)+1                              | R1  | K5              |
|                             | Point 2   | (s2)+2                              | R2  | K20             |
|                             | Point 3   | (s2)+3                              | R3  | K50             |
|                             | Point 4*1 | (s2)+4                              | R4  | K200            |

|                             | Point 9*2 | (s2)+19                             | R19 | K30             |
|                             | Point 10  | (s2)+20                             | R20 | K7              |

- \*1 When coordinates are specified using three points as shown in the points 4, 5 and 6, the output value can be set to an intermediate value.  
In this example, the output value (intermediate value) is specified by the Y coordinate of the point 5.  
Even if the X coordinate is the same at three points or more, the value at the second point is output.
- \*2 When coordinates are specified using two points as shown in the points 8 and 9, the output value is the Y coordinate at the next point.  
In this example, the output value is specified by the Y coordinate of the point 9.

## Program example

In the program example shown below, the value input to D0 is processed by scaling based on the conversion table for scaling set in R0 and later, and output to D10. It is assumed that the values for the conversion table for scaling are set in R0 and later beforehand.

### • Operation

### • Conversion table for scaling

| Set item                    | Device  | Setting contents |
|-----------------------------|---------|------------------|
| Number of coordinate points | R0      | K6               |
| X coordinate                | Point 1 | R1               |
|                             | Point 2 | R2               |
|                             | Point 3 | R3               |
|                             | Point 4 | R4               |
|                             | Point 5 | R5               |
|                             | Point 6 | R6               |
| Y coordinate                | Point 1 | R7               |
|                             | Point 2 | R8               |
|                             | Point 3 | R9               |
|                             | Point 4 | R10              |
|                             | Point 5 | R11              |
|                             | Point 6 | R12              |

## Processing details

- These instructions process the scaling conversion data (in 32-bit data units) specified by (s2) by scaling it based on the input value specified by (s1), and store the operation result in the device number specified by (d). The scaling conversion is performed based on the scaling conversion data stored in the device specified by (s2) and later.

| Setting item ("n" indicates the number of coordinate points specified by (s2).) |         | Device assignment    |

|                                                                                 | ⋮       | ⋮                    |
|                                                                                 | Point n | (s2)+4n+1, (s2)+4n   |

- If the operation result is not an integer, the number in the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in the ascending order.
- Set (s1) within the scaling conversion data range (device values of (s2) and (s2)+1).
- If the same X coordinate is specified by multiple points, the Y coordinate value of the point whose number is the largest is output.
- Set the number of coordinate points for the scaling conversion data within the range of 1 to 4294967295.

- Setting example of the conversion table for scaling

In the case of the conversion characteristics for scaling shown in the figure below, set each value as shown in the following data table.

|                             | Point 8*2 | (s2)+37, (s2)+36                    | R37, R36 | K90             |
|                             | Point 9*2 | (s2)+39, (s2)+38                    | R39, R38 | K30             |
|                             | Point 10  | (s2)+41, (s2)+40                    | R41, R40 | K7              |

- \*1 When coordinates are specified using three points as shown in the points 4, 5 and 6, the output value can be set to an intermediate value.  
In this example, the output value (intermediate value) is specified by the Y coordinate of the point 5.  
Even if the X coordinate is the same at three points or more, the value at the second point is output.
- \*2 When coordinates are specified using two points as shown in the points 8 and 9, the output value is the Y coordinate at the next point.  
In this example, the output value is specified by the Y coordinate of the point 9.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# 8.14 Special Timer Instruction

## Teaching timer

### TTMR

FX5S FX5UJ FX5U FX5UC

This instruction measures the period of time in which TTMR instruction is ON.  
Use this instruction to adjust the set value of a timer by a pushbutton switch.

| Ladder diagram                                                                    | Structured text    |
|-----------------------------------------------------------------------------------|--------------------|
|  | ENO:=TTMR(EN,s,d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                | Range  | Data type            | Data type (label)                      |
|---------|--------------------------------------------|--------|----------------------|----------------------------------------|
| (d)     | Device storing the teaching data           | —      | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 2) |
| (s)     | Magnification applied to the teaching data | 0 to 2 | 16-bit signed binary | ANY16                                  |
| EN      | Execution condition                        | —      | Bit                  | BOOL                                   |
| ENO     | Execution result                           | —      | Bit                  | BOOL                                   |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|

| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (s)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

#### ■Control data

| Operand: (d) |                                                |               |        |
|--------------|------------------------------------------------|---------------|--------|
| Device       | Description                                    | Setting range | Set by |
| +0           | Teaching time                                  | —             | System |
| +1           | Current value of the pressing and holding time | —             | System |

## Processing details

- This instruction measures the period of time to press and hold the command input (pushbutton switch) in 1-second units, multiplies the measured value by the magnification ( $10^s$ ) which is specified by (s), and stores it in the device specified by (d).

- The table below shows the actual value indicated by (d) depending on the magnification specified by (s) and the pressing and holding time  $\tau_0$ .

| (s) | Magnification | (d)              |
|-----|---------------|------------------|
| K0  | $\tau_0$      | $(d) \times 1$   |
| K1  | $10\tau_0$    | $(d) \times 10$  |
| K2  | $100\tau_0$   | $(d) \times 100$ |

## Precautions

- When the command contact turns from on to off, the current value (d)+1 of the pressing and holding time is cleared, and the teaching time (d) will not change any more.
- Two devices are occupied from a device specified as the teaching time (d). Make sure that such devices are not used in other controls for the machine.

## Program example

- Writing the teaching time to 10 types of data registers

Suppose that the set value is written to D400 to D409 in advance.

10 timers to be set

Because the timers T0 to T9 are set to 100 ms, the actual operating time (sec) is 1/10 of the teaching data.

Selecting a timer by a digital switch

An input to the 1-digit digital switch connected to X0 to X3 is converted into binary format, and transferred to Z0.

Measuring the teaching time

The time (sec) in which X10 is pressed and held is stored to D300.

Recovery of the teaching time is detected.

Writing the set value of a timer

The teaching time (D300) is transferred to the device (D400Z0) for setting a timer selected by the digital switch.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| 2820H                      | The device range specified by (d) exceeds the corresponding device range. |
| 3405H                      | The value specified by (s) is outside the following range.<br>0 to 2      |

# Special function timer

## STMR

FX5S

FX5UJ

FX5U

FX5UC

This instruction uses the four devices from the device specified by (d) to perform four types of timer output.

| Ladder diagram | Structured text                   |
|----------------|-----------------------------------|
|                | <pre>ENO:=STMR(EN,s1,s2,d);</pre> |

\*1 Only T can be used.

\*2 T, ST, and C cannot be used.

### ■Control data

| Operand: (d) |                                                                                                                                                                                                                               |               |        |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| Device       | Description                                                                                                                                                                                                                   | Setting range | Set by |
| +0           | Off delay timer output:<br>Turns on at the rising edge of the command of the STMR instruction and turns off when the time specified by (s2) elapses after the falling edge.                                                   | —             | System |
| +1           | One-shot timer output after turning off:<br>Turns on at the falling edge of the command of the STMR instruction and turns off when the time specified by (s2) elapses.                                                        | —             | System |
| +2           | One-shot timer output after turning on<br>Turns on at the rising edge of the command of the STMR instruction and turns off when the command of the STMR instruction is turned off or when the time specified by (s2) elapses. | —             | System |
| +3           | On delay timer + Off delay timer output:<br>Turns on at the falling edge of the timer coil and turns off when the time specified by (s2) elapsed after the falling edge of the command of the STMR instruction.               | —             | System |

## Processing details

- This instruction uses the four devices from the device specified by (d) to perform four types of timer output.

(1): Command of the STMR instruction

(2): Setting value specified by (s2)

- The flickering effect is produced using (d)+1 and (d)+2 with the following program (T10 is assigned to (s1), K100 is assigned to (s2), and M0 is assigned to (d)), which turns on/off the STMR instruction at the normally closed contact of (d)+3.

- A value in the range of 0 to 32767 (0 to 3276.7 seconds) can be specified in (s2).

## Precautions

- The timer number specified in this instruction cannot be used in other general circuits (such as OUT instruction). If the timer number is used in other general circuits, the timer malfunctions.
- The timer specified by (s1) starts counting as a 100 ms timer on the rising edge of the command contact.
- Four devices are occupied from a device specified in (d). Make sure that such devices are not used in other controls for the machine.
- If the command contact is turned off, (d), (d)+1, and (d)+3 turn off when the set time elapses. (d)+2 and the timer (s1) are immediately reset.

## Operation error

## Signed 32-bit bi-directional counters

### UDCNTF

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction increments the current value of the counter specified by (d) by 1 when the operation result up to UDCNTF instruction changes from OFF to ON, and when the counter reaches the end of its count, NO contact becomes turns ON and NC contact becomes turns OFF. When the long counter specified by (d) is a high-speed counter, the instruction operates to start and stop the high-speed counter.

The high-speed pulse input/output module is not supported.

For details on the high-speed counter, refer to [MELSEC iQ-F FX5 User's Manual \(Application\)](#).

| Ladder diagram | Structured text         |

|                | ENO:= UDCNTF(EN, s, d); |
| FBD/LD         |                         |
|                |                         |

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description            | Range                     | Data type            | Data type (label)     |
|---------|------------------------|---------------------------|----------------------|-----------------------|
| (d)     | Long counter number    | —                         | Device name          | ANY32                 |
| (s)     | Long counter set value | -2147483648 to 2147483647 | 32-bit signed binary | ANY32_S <sup>*1</sup> |
| EN      | Execution condition    | —                         | Bit                  | BOOL                  |
| ENO     | Execution result       | —                         | Bit                  | BOOL                  |

<sup>\*1</sup> Digit specified bit type label cannot be used.

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant        |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|-----------------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H            | E | \$ |        |
| (d)     | —                           | —                         | —     | — | ○           | —  | —                      | —               | — | —  | —      |
| (s)     | —                           | ○ <sup>*1</sup>           | ○     | — | —           | —  | —                      | ○ <sup>*2</sup> | — | —  | —      |

<sup>\*1</sup> T, ST, and C cannot be used.

<sup>\*2</sup> Only decimal constant (K) can be used.

## Processing details

- This instruction increments the current value of the counter specified by (d) by 1 when the operation result up to UDCNTF instruction changes from OFF to ON, and when the counter reaches the end of its count, NO contact becomes turns ON and NC contact becomes turns OFF.
- When the long counter specified by (d) is a high-speed counter, the instruction operates to start and stop the high-speed counter, and the current counter value is updated by turning ON/OFF an external input instead of the drive contact. Counting up or down can be switched by whether the supported special device (SM4580 to SM4595) is on or off.
- When the long counter specified by (d) is a normal counter, the counting direction of LC0 to LC34 can be switched by turning on or off the corresponding special device (SM8200 to SM8234). For LC35 or later, only up counting is supported.
- During up-counting, the output contact turns ON when the current value changes from a value less than the set value to a value not less than the set value.
- During down-counting, the output contact turns OFF when the current value changes from a value not less than the set value to a value equivalent to the "set value -1" or less.
- Counting is continued also when the drive contact changes from OFF to ON after the output contact changes. (Only when specify other than a high-speed counter for (d))
- When unsigned (0 to 4294967295) is assigned to the LC, the OUT LC instruction is used. For the OUT LC instruction, refer to  Page 137 OUT LC.
- The current value operates as a ring counter.

(1): Up counting  
(2): Down counting

## Precautions

- The last number of a word device cannot be input as the long counter set value.
- Indirect specification cannot be input as the long counter set value.
- When the set value or more is written to the current value of the up counter by the DMOV instruction, the counter is counted but the output contact does not turn on.
- When the value less than the set value is written to the current value of the down counter by the DMOV instruction, the counter is counted but the output contact does not turn off.
- When the long counter is cleared by the RST instruction, the current value will be cleared, and the contact will be turned off. After the counter is cleared, the counter will not count under the UDCNTF instruction until the RST instruction is executed in the contact OFF status.

## Operation error

There is no operation error.

# 8.16 Shortcut Control Instruction

## Rotary table shortest direction control

### ROTC

FX5S

FX5UJ

FX5U

FX5UC

This instruction is suitable for efficient control of the rotary table for putting/taking a product on/off the rotary table.

## Processing details

- The table rotation is controlled by conditions of "n2", (s), and (d) so that a product can be efficiently put on or taken off the rotary table divided into "n1" (=10) sections as shown in the figure below. When the following conditions are specified, forward/backward rotation and high-speed/low-speed/stop are output to (d)+3 to (d)+7.

- Provide a 2-phase switch (X0 and X1) for detecting the rotation direction (forward or backward) of the table and the switch X2 which turns ON when the product No. 0 reaches the station No. 0. X0 to X2 are replaced with internal contacts of (d) to (d)+2. Any head device number can be specified by X or (d).

- The counter (s) detects which product number is located at the station No. 0.
- Set the station No. to be called in (s)+1.
- Set the product No. to be called in (s)+2.
- Specify the number of divisions (n1) of the table, and number of low-speed sections (n2).

## Precautions

- When the command input is set to ON and this instruction is executed, the result will be automatically output to (d)+3 to (d)+7. When the command input is set to OFF, (d)+3 to (d)+7 are set to OFF accordingly.
- For example, when the rotation detection signal ((d) to (d)+2) is activated 10 times in one division, set a value multiplied by "10" to each division, station No. to be called and product No. to be called. As a result, an intermediate value of the division number can be set to a low-speed section.
- When the zero point detection signal (M2) turns ON while the command input is ON, the contents of the register for counting (s) are cleared to "0". This clear operation should be executed before starting the operation.
- Up to four ROTC instructions can be used simultaneously.

## Operation error

## Processing details

- When the start value (s1) and the end value (s2) have been specified and the command input is set to ON, the value obtained by adding a value divided equally by "n" times to (s1) in the next operation cycle is stored to (d). By combining this instruction and an analog output, the cushion start/stop command can be output.

- The number of scans ("0" to "n") is stored in  $(d)+1$ .
- The time from start to the end value is the operation cycle multiplied by "n" times.
- If the command input is set to OFF in the middle of operation, execution is paused. (The current value stored in  $(d)$  is held, and the number of scans stored in  $(d)+1$  is cleared.) When the command input is set to ON again,  $(d)$  is cleared, and the operation is started from  $(s1)$ .
- After transfer is completed, the instruction execution complete flag SM8029 turns ON, and the  $(d)$  value is returned to the  $(s1)$  value.

- When the operation result is acquired at a constant time interval (constant scan mode), write a prescribed scan time (which is longer than the actual scan time) to SD8039 and set SM8039 to ON. For example, when "20 ms" is written to SD8039 and "n" is set to 100, the  $(d)$  value will change from  $(s1)$  to  $(s2)$  in 2 seconds.
- The value used in the constant scan mode can be set in the parameter setting of an engineering tool (constant scan execution interval setting of CPU parameter).

For details on the constant scan, refer to MELSEC iQ-F FX5 User's Manual (Application).

For details on the engineering tool, refer to GX Works3 Operating Manual.

- The contents of (d) are changed as follows depending on the ON/OFF status of the mode flag SM8026.

Precautions

To specify a latched (battery backed) type device as (d) when setting the CPU module to the RUN mode while the command input is ON, clear (d) in advance.

Operation error

### Measuring the density of 16 bit binary pulses

#### SPD

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

This instruction counts the number of times the device input specified by (s1) turns off → on only for the time (in 16-bit data units) specified by (s2) × 1ms and stores the operation result in the device specified by (d). The high-speed pulse input/output module is not supported.

|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s1)    | ○*1                         | ○*2                       | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | —                           | ○                         | —     | ○ | —           | —  | ○                      | —        | — | —  | —      |

\*1 Only X can be used for a bit device. Designate with the following range.

- FX5S/FX5UJ CPU module: X0 to X7

- FX5U/FX5UC CPU module: X0 to X17

Note that bit device digit designation cannot be used.

\*2 When a word device is specified, specify one of the channel numbers (CH1 to CH8).

When FX3 compatible function of a high-speed counter is valid, a channel number cannot be specified. Only X can be used for a bit device.

If the channel numbers is specified in (s1), an error occurs.

## Processing details

- This instruction counts the number of times the device input specified by (s1) turns off → on only for the time (in 16-bit data units) specified by (s2) × 1ms and stores the operation result in the device specified by (d).

(1): The elapsed time is judged using the 1ms interrupt and the counted result is stored in (d).

- The channel number of the high-speed counter specified by (s1) interlocks with the channel number in which parameters are set.
- When a word device is specified by (s1), this instruction counts the number of pulses by the high-speed counter setting of the channel number corresponding to each word device.
- When a bit device is specified by (s1), the following input assignment devices (shaded area) are valid.
- When the high-speed counter FX3 compatibility function is enabled, only the 1-phase 1-input pulse input mode (S/W) (general-purpose input assignment of the 1-phase 1-input counter (switching S/W up or down)) is enabled.

## Precautions

- The maximum input frequency of turning the inputs ON and OFF is shown below:

■ FX5S/FX5UJ CPU module

| Used input number | Maximum input frequency |
|-------------------|-------------------------|
| X0, X1, X3, X4    | 100 kHz                 |
| X2, X5, X6, X7    | 10 kHz                  |

■ FX5U-32M□/ FX5UC-32M□ CPU module

| Used input number | Maximum input frequency |
|-------------------|-------------------------|
| X0 to X5          | 200 kHz                 |
| X6, X7            | 10 kHz                  |

■ FX5U-64M□/FX5U-80M□/FX5UC-64M□/FX5UC-96M□ CPU module

| Used input number | Maximum input frequency |
|-------------------|-------------------------|
| X0 to X7          | 200 kHz                 |
| X10 to X17        | 10 kHz                  |

- When the SPD instruction is used, the UP/DOWN pulse input, preset input and enable input operate in accordance with the contents set by the parameters of the high-speed counter.
- When the measurement time is changed while the SPD instruction is executed, the changed time is applied every time the measurement time ends.
- When the current value of the high-speed counter is overwritten, a preset input is executed, or the high-speed counter is reset by the DHCMOV instruction while the SPD instruction is executed, the operation continues, but the pulse density cannot be measured normally.
- When the SPD instruction is used, pulses per unit time which exceeds the ring length of the high-speed counter cannot be input. When pulses are input, the pulse density cannot be measured normally.
- The measurement time specified by (s2) overwrites the value stored in the SD device specified for the measurement unit time.
- When the measurement time specified by (s2) is outside the range from 1 to 32767, the specified measurement time is rounded into "1" with the sign.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------------------|

\*1 Digit specified bit type label cannot be used.

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s1)    | ○ <sup>*1</sup>             | ○ <sup>*2</sup>           | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | —                           | ○                         | —     | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

\*1 Only X can be used for a bit device. Designate with the following range.

- FX5S/FX5UJ CPU module: X0 to X7
- FX5U/FX5UC CPU module: X0 to X17

Note that bit device digit designation cannot be used.

\*2 When a word device is specified, specify one of the channel numbers (CH1 to CH8).

When FX3 compatible function of a high-speed counter is valid, a channel number cannot be specified. Only X can be used for a bit device.

If the channel numbers is specified in (s1), an error occurs.

## Processing details

- This instruction counts the number of times the device input specified by (s1) turns off → on only for the time (in 32-bit data units) specified by (s2) × 1ms and stores the operation result in the device specified by (d).

(1): The elapsed time is judged using the 1ms interrupt and the counted result is stored in (d)+1 and (d).

- The channel number of the high-speed counter specified by (s1) interlocks with the channel number in which parameters are set.
- When a word device is specified by (s1), this instruction counts the number of pulses by the high-speed counter setting of the channel number corresponding to each word device.
- When a bit device is specified by (s1), the following input assignment devices (shaded area) are valid.
- When the high-speed counter FX3 compatibility function is enabled, only the 1-phase 1-input pulse input mode (S/W) (general-purpose input assignment of the 1-phase 1-input counter (switching S/W up or down)) is enabled.

### [FX5S/FX5UJ CPU module]

#### General-purpose input assignment of the 1-phase 1-input counter (switching S/W up or down)

## Precautions

- The maximum input frequency of turning the inputs ON and OFF is shown below:

■FX5S/FX5UJ CPU module

| Used input number | Maximum input frequency |
|-------------------|-------------------------|
| X0, X1, X3, X4    | 100 kHz                 |
| X2, X5, X6, X7    | 10 kHz                  |

■FX5U-32M□/FX5UC-32M□ CPU module

| Used input number | Maximum input frequency |
|-------------------|-------------------------|
| X0 to X5          | 200 kHz                 |
| X6, X7            | 10 kHz                  |

■FX5U-64M□/FX5U-80M□/FX5UC-64M□/FX5UC-96M□ CPU module

| Used input number | Maximum input frequency |
|-------------------|-------------------------|
| X0 to X7          | 200 kHz                 |
| X10 to X17        | 10 kHz                  |

- When the DSPD instruction is used, the UP/DOWN pulse input, preset input and enable input operate in accordance with the contents set by the parameters of the high-speed counter.
- When the measurement time is changed while the DSPD instruction is executed, the changed time is applied every time the measurement time ends.
- When the current value of the high-speed counter is overwritten, a preset input is executed, or the high-speed counter is reset by the DHCMOV instruction while the DSPD instruction is executed, the operation continues, but the pulse density cannot be measured normally.
- When the DSPD instruction is used, pulses per unit time which exceeds the ring length of the high-speed counter cannot be input. When pulses are input, the pulse density cannot be measured normally.
- The measurement time specified by (s2) overwrites the value stored in the SD device specified for the measurement unit time.
- When the measurement time specified by (s2) is outside the range from 1 to 2147483647, the specified measurement time is rounded into "1" with the sign.

## Operation error

# 16 bit binary pulse output

## PLSY [For the FX3 compatible operand specification]

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

This instruction outputs 16-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 16-bit pulses specified by the positioning address (n). Only CPU module is supported.

\*1 FX5S/FX5U/FX5UC CPU module: Only Y0 to Y3 devices can be used.  
FX5UJ CPU module: Only Y0 to Y2 devices can be used.

## Processing details

- This instruction outputs 16-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 16-bit pulses specified by the positioning address (n).

- Set the value from 0 to 65535 (in user unit) to the command speed (s), so that the command speed is 200 kpps or less when the command speed is converted to frequency.
- Set the value from 0 to 65535 (in user unit) to the positioning address (n), so that the positioning address is within the range from 0 to 2147483647 when the positioning address is converted to number of pulses.
- Specify the following Y device number in (d).
  - FX5S/FX5U/FX5UC CPU module: Y0 to Y3
  - FX5UJ CPU module: Y0 to Y2
- The following tables show the special relays and special registers related to the PLSY instruction.

[Special relays]

| Axis number |        |        |        | Name                                          | Descriptions                                                               |
|-------------|--------|--------|--------|-----------------------------------------------|----------------------------------------------------------------------------|
| 1           | 2      | 3      | 4      |                                               |                                                                            |
| SM5500      | SM5501 | SM5502 | SM5503 | Positioning instruction activation            | ON: During activation, OFF: Not activated                                  |
| SM5516      | SM5517 | SM5518 | SM5519 | Pulse output monitor                          | ON: During output, OFF: During stop                                        |
| SM5532      | SM5533 | SM5534 | SM5535 | Positioning error occurrence                  | ON: Error occurred, OFF: Error not occurred                                |
| SM5628      | SM5629 | SM5630 | SM5631 | Pulse output stop command                     | ON: Stop command is on, OFF: Stop command is off                           |
| SM5644      | SM5645 | SM5646 | SM5647 | Pulse deceleration stop command <sup>*1</sup> | ON: Deceleration stop command is on, OFF: Deceleration stop command is off |
| SM5660      | SM5661 | SM5662 | SM5663 | Forward limit                                 | ON: Forward limit is on, OFF: Forward limit is off                         |
| SM5676      | SM5677 | SM5678 | SM5679 | Reverse limit                                 | ON: Reverse limit is on, OFF: Reverse limit is off                         |

<sup>\*1</sup> Because the PLSY instruction does not have the acceleration/deceleration function, the operation is stopped immediately even though the pulse deceleration stop command is turned on.

## Precautions

- The operation cannot be performed normally in an environment such as user program where the instruction cannot be executed at each scan or if the instruction is jumped by the CJ(P) instruction. However, the pulse output is continued.
- The same devices as the ones of position instruction, PWM output or general-purpose output cannot be used for the output in the PLSY instruction.
- When the pulse output is stopped, the operation is stopped immediately by the PLSY instruction. Note that the motor is stopped without deceleration and this may damage the system. For stopping method of the pulse output, refer to [MELSEC iQ-F FX5 User's Manual \(Application\)](#).
- If the positioning address is 0 when the PLSY instruction is activated, pulses are output without limitation.
- Overwrite the positioning address during the pulse output to change the positioning address in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten. The positioning address becomes invalid if it is changed from 0 to a value other than 0 or from a value other than 0 to 0 during positioning operation.
- When the positioning address is changed during the pulse output, the operation is stopped immediately if the changed value is the number of pulses which have already been output or less.
- Overwrite the command speed during the pulse output to change the command speed in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten.
- When the numbers of pulses (by the pulses conversion) of the command speed and positioning address exceed the 32-bit range, an error occurs and the operation cannot be performed.
- The PLSY instruction always increases the current address because the setting of rotation direction is disabled due to the absence of direction.
- When the output mode is CW/CCW mode, output is always performed from the device set to CW.
- If reverse limit is used, it operates as forward limit.
- Do not set the value of 200 kpps or more by the frequency conversion when changing the command speed during the pulse output.
- If the command speed is set to 0 when the PLSY instruction is activated, the operation ends with an error and stops pulse output.
- If the command speed is changed to 0 during pulse output, the operation immediately stops without abnormal end flag. However, if the drive contact is not turned off, pulse output will restart when the command speed is changed.
- The command speed is changed to negative value during pulse output, it is the operation ends with an error.
- The following table shows the operation timing of the complete flag and abnormal end flag of the PLSY instruction.

|                  | Complete flag (SM8029)                                                                                                                                                                                                                               | Abnormal end flag (SM8329)                                                                                                                                                                                                                                                                                                                                                                                                                 |

## PLSY [For the FX5 operand specification]

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

This instruction outputs 16-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 16-bit pulses specified by the positioning address (n). Only CPU module is supported.

## Processing details

- This instruction outputs 16-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 16-bit pulses specified by the positioning address (n).

- Set the value from 0 to 65535 (in user unit) to the command speed (s), so that the command speed is 200 kpps or less when the command speed is converted to frequency.
- Set the value from 0 to 65535 (in user unit) in the positioning address (n), so that the positioning address is within the range from 0 to 2147483647 when the positioning address is converted to number of pulses.
- Specify the axis number (K1 to K4) in which positioning parameters exist in (d).
- The following tables show the special relays and special registers related to the PLSY instruction.

[Special relays]

| Axis number |        |        |        | Name                                          | Descriptions                                                               |
|-------------|--------|--------|--------|-----------------------------------------------|----------------------------------------------------------------------------|
| 1           | 2      | 3      | 4      |                                               |                                                                            |
| SM5500      | SM5501 | SM5502 | SM5503 | Positioning instruction activation            | ON: During activation, OFF: Not activated                                  |
| SM5516      | SM5517 | SM5518 | SM5519 | Pulse output monitor                          | ON: During output, OFF: During stop                                        |
| SM5532      | SM5533 | SM5534 | SM5535 | Positioning error occurrence                  | ON: Error occurred, OFF: Error not occurred                                |
| SM5628      | SM5629 | SM5630 | SM5631 | Pulse output stop command                     | ON: Stop command is on, OFF: Stop command is off                           |
| SM5644      | SM5645 | SM5646 | SM5647 | Pulse deceleration stop command <sup>*1</sup> | ON: Deceleration stop command is on, OFF: Deceleration stop command is off |
| SM5660      | SM5661 | SM5662 | SM5663 | Forward limit                                 | ON: Forward limit is on, OFF: Forward limit is off                         |
| SM5676      | SM5677 | SM5678 | SM5679 | Reverse limit                                 | ON: Reverse limit is on, OFF: Reverse limit is off                         |

<sup>\*1</sup> Because the PLSY instruction does not have the acceleration/deceleration function, the operation is stopped immediately even though the pulse deceleration stop command is turned on.

## Precautions

- The operation cannot be performed normally in an environment such as user program where the instruction cannot be executed at each scan or if the instruction is jumped by the CJ(P) instruction. However, the pulse output is continued.
- The same devices as the ones of position instruction, PWM output or general-purpose output cannot be used for the output in the PLSY instruction.
- When the pulse output is stopped, the operation is stopped immediately by the PLSY instruction. Note that the motor is stopped without deceleration and this may damage the system. For stopping method of the pulse output, refer to  MELSEC iQ-F FX5 User's Manual (Application).
- If the positioning address is 0 when the PLSY instruction is activated, pulses are output without limitation.
- Overwrite the positioning address during the pulse output to change the positioning address in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten. The positioning address becomes invalid if it is changed from 0 to a value other than 0 or from a value other than 0 to 0 during positioning operation.
- When the positioning address is changed during the pulse output, the operation is stopped immediately if the changed value is the number of pulses which have already been output or less.
- Overwrite the command speed during the pulse output to change the command speed in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten.
- When the numbers of pulses (by the pulses conversion) of the command speed and positioning address exceed the 32-bit range, an error occurs and the operation cannot be performed.
- The PLSY instruction always increases the current address because the setting of rotation direction is disabled due to the absence of direction.
- When the output mode is CW/CCW mode, output is always performed from the device set to CW.
- If reverse limit is used, it operates as forward limit.
- Do not set the value of 200 kpps or more by the frequency conversion when changing the command speed during the pulse output.
- If the command speed is set to 0 when the PLSY instruction is activated, the operation ends with an error and stops pulse output.
- If the command speed is changed to 0 during pulse output, the operation immediately stops without abnormal end flag. However, if the drive contact is not turned off, pulse output will restart when the command speed is changed.
- The command speed is changed to negative value during pulse output, it is the operation ends with an error.
- The following table shows the operation timing of the complete flag and abnormal end flag of the PLSY instruction.

|                  | Complete flag (SM8029)                                                                                                                                                                                                                                 | Abnormal end flag (SM8329)                                                                                                                                                                                                                                                                                                                                                                                                      |

\*1 The flag turns on only during one scan time when the activation contact of the instruction turns off and on.

## Operation error

| 3661H                      | 3662H  | 3663H  | 3664H  | The operation decelerates and stops by the pulse output stop command or special relay whose all outputs are disabled during the pulse output or at the activating of the positioning.    |

# 32 bit binary pulse output

## DPLSY [For the FX3 compatible operand specification]

FX5S

FX5UJ

FX5U

FX5UC

This instruction outputs 32-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 32-bit pulses specified by the positioning address (n). Only CPU module is supported.

\*1 FX5S/FX5U/FX5UC CPU module: Only Y0 to Y3 devices can be used.  
 FX5UJ CPU module: Only Y0 to Y2 devices can be used.

## Processing details

- This instruction outputs 32-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 32-bit pulses specified by the positioning address (n).

- Set the value from 0 to 2147483647 (in user unit) to the command speed (s), so that the command speed is 200 kpps or less when the command speed is converted to frequency.

- Set the value from 0 to 2147483647 (in user unit) to the positioning address (n), so that the positioning address is within the range from 0 to 2147483647 when the positioning address is converted to number of pulses.
- Specify the following Y device number in (d).
  - FX5S/FX5U/FX5UC CPU module: Y0 to Y3
  - FX5UJ CPU module: Y0 to Y2
- The following tables show the special relays and special registers related to the DPLSY instruction.

[Special relays]

| Axis number |        |        |        | Name                                          | Descriptions                                                               |
|-------------|--------|--------|--------|-----------------------------------------------|----------------------------------------------------------------------------|
| 1           | 2      | 3      | 4      |                                               |                                                                            |
| SM5500      | SM5501 | SM5502 | SM5503 | Positioning instruction activation            | ON: During activation, OFF: Not activated                                  |
| SM5516      | SM5517 | SM5518 | SM5519 | Pulse output monitor                          | ON: During output, OFF: During stop                                        |
| SM5532      | SM5533 | SM5534 | SM5535 | Positioning error occurrence                  | ON: Error occurred, OFF: Error not occurred                                |
| SM5628      | SM5629 | SM5630 | SM5631 | Pulse output stop command                     | ON: Stop command is on, OFF: Stop command is off                           |
| SM5644      | SM5645 | SM5646 | SM5647 | Pulse deceleration stop command <sup>*1</sup> | ON: Deceleration stop command is on, OFF: Deceleration stop command is off |
| SM5660      | SM5661 | SM5662 | SM5663 | Forward limit                                 | ON: Forward limit is on, OFF: Forward limit is off                         |
| SM5676      | SM5677 | SM5678 | SM5679 | Reverse limit                                 | ON: Reverse limit is on, OFF: Reverse limit is off                         |

<sup>\*1</sup> Because the DPLSY instruction does not have the acceleration/deceleration function, the operation is stopped immediately even though the pulse deceleration stop command is turned on.

## Precautions

- The operation cannot be performed normally in an environment such as user program where the instruction cannot be executed at each scan or if the instruction is jumped by the CJ(P) instruction. However, the pulse output is continued.
- The same devices as the ones of position instruction, PWM output or general-purpose output cannot be used for the output in the DPLSY instruction.
- When the pulse output is stopped, the operation is stopped immediately by the DPLSY instruction. Note that the motor is stopped without deceleration and this may damage the system. For stopping method of the pulse output, refer to [MELSEC iQ-F FX5 User's Manual \(Application\)](#).
- If the positioning address is 0 when the DPLSY instruction is activated, pulses are output without limitation.
- Overwrite the positioning address during the pulse output to change the positioning address in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten. The positioning address becomes invalid if it is changed from 0 to a value other than 0 or from a value other than 0 to 0 during positioning operation.
- When the positioning address is changed during the pulse output, the operation is stopped immediately if the changed value is the number of pulses which have already been output or less.
- Overwrite the command speed during the pulse output to change the command speed in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten.
- When the numbers of pulses (by the pulses conversion) of the command speed and positioning address exceed the 32-bit range, an error occurs and the operation cannot be performed.
- The DPLSY instruction always increases the current address because the setting of rotation direction is disabled due to the absence of direction.
- When the output mode is CW/CCW mode, output is always performed from the device set to CW.
- If reverse limit is used, it operates as forward limit.
- Do not set the value of 200 kpps or more by the frequency conversion when changing the command speed during the pulse output.
- If the command speed is set to 0 when the DPLSY instruction is activated, the operation ends with an error and stops pulse output.
- If the command speed is changed to 0 during pulse output, the operation immediately stops without abnormal end flag. However, if the drive contact is not turned off, pulse output will restart when the command speed is changed.
- The command speed is changed to negative value during pulse output, it is the operation ends with an error.
- The following table shows the operation timing of the complete flag and abnormal end flag of the DPLSY instruction.

|                  | Complete flag (SM8029)                                                                                                                                                                                                                                 | Abnormal end flag (SM8329)                                                                                                                                                                                                                                                                                                                                                                                                                 |

<sup>\*1</sup> The flag turns on only during one scan time when the activation contact of the instruction turns off and on.

## Program example

When (n) is set to K0, pulses are output without any limitation.

## Operation error

## DPLSY [For the FX5 operand specification]

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

This instruction outputs 32-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 32-bit pulses specified by the positioning address (n). Only CPU module is supported.

## Processing details

- This instruction outputs 32-bit pulse trains specified by the command speed (s) from the device specified by the output (d) for the amount of 32-bit pulses specified by the positioning address (n).

- Set the value from 0 to 2147483647 (in user unit) to the command speed (s), so that the command speed is 200 kpps or less when the command speed is converted to frequency.
- Set the value from 0 to 2147483647 (in user unit) to the positioning address (n), so that the positioning address is within the range from 0 to 2147483647 when the positioning address is converted to number of pulses.
- Specify the axis number (K1 to K4) in which positioning parameters exist in (d).
- The following tables show the special relays and special registers related to the DPLSY instruction.

[Special relays]

| Axis number |        |        |        | Name                                          | Descriptions                                                               |
|-------------|--------|--------|--------|-----------------------------------------------|----------------------------------------------------------------------------|
| 1           | 2      | 3      | 4      |                                               |                                                                            |
| SM5500      | SM5501 | SM5502 | SM5503 | Positioning instruction activation            | ON: During activation, OFF: Not activated                                  |
| SM5516      | SM5517 | SM5518 | SM5519 | Pulse output monitor                          | ON: During output, OFF: During stop                                        |
| SM5532      | SM5533 | SM5534 | SM5535 | Positioning error occurrence                  | ON: Error occurred, OFF: Error not occurred                                |
| SM5628      | SM5629 | SM5630 | SM5631 | Pulse output stop command                     | ON: Stop command is on, OFF: Stop command is off                           |
| SM5644      | SM5645 | SM5646 | SM5647 | Pulse deceleration stop command <sup>*1</sup> | ON: Deceleration stop command is on, OFF: Deceleration stop command is off |
| SM5660      | SM5661 | SM5662 | SM5663 | Forward limit                                 | ON: Forward limit is on, OFF: Forward limit is off                         |
| SM5676      | SM5677 | SM5678 | SM5679 | Reverse limit                                 | ON: Reverse limit is on, OFF: Reverse limit is off                         |

<sup>\*1</sup> Because the DPLSY instruction does not have the acceleration/deceleration function, the operation is stopped immediately even though the pulse deceleration stop command is turned on.

## Precautions

- The operation cannot be performed normally in an environment such as user program where the instruction cannot be executed at each scan or if the instruction is jumped by the CJ(P) instruction. However, the pulse output is continued.
- The same devices as the ones of position instruction, PWM output or general-purpose output cannot be used for the output in the DPLSY instruction.
- When the pulse output is stopped, the operation is stopped immediately by the DPLSY instruction. Note that the motor is stopped without deceleration and this may damage the system. For stopping method of the pulse output, refer to  MELSEC iQ-F FX5 User's Manual (Application).
- If the positioning address is 0 when the DPLSY instruction is activated, pulses are output without limitation.
- Overwrite the positioning address during the pulse output to change the positioning address in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten. The positioning address becomes invalid if it is changed from 0 to a value other than 0 or from a value other than 0 to 0 during positioning operation.
- When the positioning address is changed during the pulse output, the operation is stopped immediately if the changed value is the number of pulses which have already been output or less.
- Overwrite the command speed during the pulse output to change the command speed in operation. The written value is reflected at the first time that the instruction is executed after the device is overwritten.
- When the numbers of pulses (by the pulses conversion) of the command speed and positioning address exceed the 32-bit range, an error occurs and the operation cannot be performed.
- The DPLSY instruction always increases the current address because the setting of rotation direction is disabled due to the absence of direction.
- When the output mode is CW/CCW mode, output is always performed from the device set to CW.
- If reverse limit is used, it operates as forward limit.
- Do not set the value of 200 kpps or more by the frequency conversion when changing the command speed during the pulse output.
- If the command speed is set to 0 when the DPLSY instruction is activated, the operation ends with an error and stops pulse output.
- If the command speed is changed to 0 during pulse output, the operation immediately stops without abnormal end flag. However, if the drive contact is not turned off, pulse output will restart when the command speed is changed.
- The command speed is changed to negative value during pulse output, it is the operation ends with an error.
- The following table shows the operation timing of the complete flag and abnormal end flag of the DPLSY instruction.

|                  | Complete flag (SM8029)                                                                                                                                                                                                                                 | Abnormal end flag (SM8329)                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# 16 bit binary pulse width modulation

## PWM

FX5S

FX5UJ

FX5U

FX5UC

This instruction outputs the pulse (in 16-bit data units) of the ON time (in 16-bit data units) specified by (s1) and the period specified by (s2) to the output destination specified by (d).

\*1 Only Y can be used for a bit device.

When a bit device is specified, specify one of Y0 to Y7. The high-speed pulse input/output module bit device (Y) cannot be specified. If Y is specified, outputs are enabled when there is an unused channel number in the parameter setting and the specified Y number is not used.

The nibble of a bit device cannot be specified.

\*2 When a word device or constant is specified, specify one of the channel numbers.

Specify K1 to K4 (axis 1 to 4) for the CPU module, and K5 to K12 (axis 5 to 12) for the high-speed pulse input/output module.

## Processing details

- This instruction outputs the pulse of the ON time specified by (s1) and the period specified by (s2) to the output destination specified by (d).

- Time with a unit selected on the parameter setting screen ( $\mu$ s or ms) can be specified by (s1) and (s2).
- The pulse output destination channel number selected on the parameter setting screen can be specified by (d).
- This instruction store the number of pulses, pulse width, and period output from each channel to an SD device. The pulse width and period are stored in the units set by the parameters. When 0 is specified in the pulse output, pulses are output without any limitation.

| Pulse output destination channel | Number of output pulses | R/W | Initial value | Timing of reflection on operation                                                                                                                                 | Timing of clearing to initial value |

\*1 When the DHCMOV instruction is used, the latest value can be read. A writable device can be updated immediately.

\*2 Parameter setting values are set to an SD device at STOP to RUN.

\*3 When this instruction is executed, the pulse width and period specified (s1) and (s2) are set to an SD device.

• After the pulse output is started from each channel, the pulse output monitor turns on.

| Pulse output destination channel | Pulse output monitor | R/W | Initial value | ON timing                                                                                                                           | OFF timing                                                                                                                                                                                          |

| CH4                              | SD5355, SD5354                                 |     |               |                                                                                                                                                                                                    |                                                                                                   |

- The number of output pulses set to an SD device is valid for this instruction as well. The setting values are always read and updated.
- When the specified number of output pulses is equal to or less than the number of pulses which have already been output, pulse output stops after outputting pulses which are being output.
- When the specified number of output pulses is larger than the number of pulses which have already been output, pulse output stops after outputting set number of pulses.
- When the number of output pulses is set from the no limitation output setting (number of output pulses is 0), the number of output pulses is not updated (because outputting pulses continues or stops in the no limitation output).
- The maximum number of output pulses which can be output when the PWM instruction is executed once (= maximum value which can be set to an SD device) is "2147483647".
- The ON time and period can be set during the pulse output. Setting values are always read and updated.
- When the number of output pulses is 0 (no limitation output setting), the monitor of the current number of output pulses is set to 0.

- When the number of output pulses is specified, the output pulses are monitored. When the PWM output is executed several times, the monitor of the number of output pulses is an integrated value.
- The monitor of the current number of output pulses can be changed during the pulse output.
- The monitor of the current number of output pulses is updated when the number of pulses is counted at the falling edge of pulses in the positive logic and at the rising edge of pulses in the negative logic.
- When the output always remains ON or OFF, the monitor of the current number of output pulses does not change.
- The maximum value of the monitor of the current number of output pulses is "FFFFFFFFH". After the current number of output pulses reaches the maximum value, the monitor of the current number of output pulses starts to count again from "0".

## Precautions

- Specify the ON time by (s1) and the period by (s2) so that [(s2)-(s1)] is equal to or larger than 3  $\mu$ s.
- Specify the ON time by (s1) and the period by (s2) so that they are equal or larger than the following values.

[FX5S/FX5UJ CPU module]

| Output number     | (s1) ON time     | (s2) Period      |
|-------------------|------------------|------------------|
| <b>CPU module</b> |                  |                  |
| Y0 to Y2          | 2 $\mu$ s more   | 5 $\mu$ s more   |
| Y3 to Y7          | 200 $\mu$ s more | 400 $\mu$ s more |

[FX5U/FX5UC CPU module and high-speed pulse input/output module]

| Output number |                                      | (s1) ON time     | (s2) Period      |
|---------------|--------------------------------------|------------------|------------------|
| CPU module    | High-speed pulse input/output module |                  |                  |
| Y0 to Y3      | Y0 to Y2                             | 2 $\mu$ s more   | 5 $\mu$ s more   |
| Y4 to Y7      | —                                    | 200 $\mu$ s more | 400 $\mu$ s more |

- When a channel number that is not selected for the PWM output in the parameter setting is specified for (d), this instruction is not executed. An operation error occurs.
- Do not specify the channel numbers of the high-speed pulse input/output module (5 to 12) in a program with interrupt priority set to "1".

- Operations when the PWM output is stopped (while the output pulse is on)

- Operations when the PWM output is stopped (while the output pulse is off)

- The PWM output stops when SM8034 is on, and starts when SM8034 is off.
- PWM output does not stop, even if a pulse stop command for positioning is driven.
- When specifying the number of output pulses, executing the PWM instruction, and then outputting pulses again after the pulse output stops due to the completion of output of the specified number of pulses, turn OFF the contact which drove the PWM instruction. When driving PWM output by the HIOEN instruction, use the HIOEN instruction to turn PWM output off.
- When the period setting is equivalent to the ON time setting, the output always remains ON. The output ON state continues even after "Period x Number of output pulses" is finished in this condition.

## Program example

When the contents of D10 are changed ranging from "0" to "50" in the program example shown below, the average output from Y0 will be ranging from 0 to 100%.

An error will occur if the contents of D10 exceed K50.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                      |

# 32 bit binary pulse width modulation

## DPWM

FX5S

FX5UJ

FX5U

FX5UC

This instruction outputs the pulse (in 32-bit data units) of the ON time (in 32-bit data units) specified by (s1) and the period specified by (s2) to the output destination specified by (d).

\*1 Only Y can be used for a bit device.

When a bit device is specified, specify one of Y0 to Y7. The high-speed pulse input/output module bit device (Y) cannot be specified. If Y is specified, outputs are enabled when there is an unused channel number in the parameter setting and the specified Y number is not used.

The nibble of a bit device cannot be specified.

\*2 When a word device or constant is specified, specify one of the CH numbers.

Specify K1 to K4 (axis 1 to 4) for the CPU module, and K5 to K12 (axis 5 to 12) for the high-speed pulse input/output module.

## Processing details

- This instruction outputs the pulse of the ON time specified by (s1) and the period specified by (s2) to the output destination specified by (d).

- Time with a unit selected on the parameter setting screen ( $\mu\text{s}$  or  $\text{ms}$ ) can be specified by (s1) and (s2).
- The pulse output destination channel number selected on the parameter setting screen can be specified by (d).
- This instruction stores the number of pulses, pulse width, and period output from each channel to an SD device. The pulse width and period are stored in the units set by the parameters. When 0 is specified in the pulse output, pulses are output without any limitation.

| Pulse output destination channel | Number of output pulses | R/W | Initial value   | Timing of reflection on operation                                                                                                                                                          | Timing of clearing to initial value |

\*1 When the DHCMOV instruction is used, the latest value can be read. A writable device can be updated immediately.

\*2 Parameter setting values are set to an SD device at STOP to RUN.

\*3 When this instruction is executed, the pulse width and period specified (s1) and (s2) are set to an SD device.

• After the pulse output is started from each channel, the pulse output monitor turns on.

| Pulse output destination channel | Pulse output monitor | R/W | Initial value | ON timing                                                                                                                                | OFF timing                                                                                                                                                                                          |

| CH4                              | SD5355, SD5354                                 |     |               |                                                                                                                                                      |                                                                                                   |

- The number of output pulses set to an SD device is valid for this instruction as well. The setting values are always read and updated.
- When the specified number of output pulses is equal to or less than the number of pulses which have already been output, pulse output stops after outputting pulses which are being output.
- When the specified number of output pulses is larger than the number of pulses which have already been output, pulse output stops after outputting set number of pulses.
- When the number of output pulses is set from the no limitation output setting (number of output pulses is 0), the number of output pulses is not updated (because outputting pulses continues or stops in the no limitation output).
- The maximum number of output pulses which can be output when the DPWM instruction is executed once (= maximum value which can be set to an SD device) is "2147483647".
- The ON time and period can be set during the pulse output. Setting values are always read and updated.
- When the number of output pulses is 0 (no limitation output setting), the monitor of the current number of output pulses is set to 0.

- When the number of output pulses is specified, the output pulses are monitored. When the DPWM output is executed several times, the monitor of the number of output pulses is an integrated value.
- The monitor of the current number of output pulses can be changed during the pulse output.
- The monitor of the current number of output pulses is updated when the number of pulses is counted at the falling edge of pulses in the positive logic and at the rising edge of pulses in the negative logic.
- When the output always remains ON or OFF, the monitor of the current number of output pulses does not change.
- The maximum value of the monitor of the current number of output pulses is "FFFFFFFFH". After the current number of output pulses reaches the maximum value, the monitor of the current number of output pulses starts to count again from "0".

## Precautions

- Specify the ON time by (s1) and the period by (s2) so that [(s2)-(s1)] is equal to or larger than 3  $\mu$ s.
- When a negative value is specified for the ON time by (s1) and the period by (s2), an operation error occurs. (In 16-bit instruction PWM, no error occurs.)
- Specify the ON time by (s1) and the period by (s2) so that they are equal or larger than the following values.

[FX5S/FX5UJ CPU module]

| Output number     | (s1) ON time     | (s2) Period      |
|-------------------|------------------|------------------|
| <b>CPU module</b> |                  |                  |
| Y0 to Y2          | 2 $\mu$ s more   | 5 $\mu$ s more   |
| Y3 to Y7          | 200 $\mu$ s more | 400 $\mu$ s more |

[FX5U/FX5UC CPU module and high-speed pulse input/output module]

| Output number     |                                             | (s1) ON time     | (s2) Period      |
|-------------------|---------------------------------------------|------------------|------------------|
| <b>CPU module</b> | <b>High-speed pulse input/output module</b> |                  |                  |
| Y0 to Y3          | Y0 to Y2                                    | 2 $\mu$ s more   | 5 $\mu$ s more   |
| Y4 to Y7          | —                                           | 200 $\mu$ s more | 400 $\mu$ s more |

- When a channel number that is not selected for the DPWM output in the parameter setting is specified for (d), this instruction is not executed. An operation error occurs.
- Do not specify the channel numbers of the high-speed pulse input/output module (5 to 12) in a program with interrupt priority set to "1".
- Operations when the DPWM output is stopped (while the output pulse is on)

- Operations when the DPWM output is stopped (while the output pulse is off)

- The PWM output stops when SM8034 is on, and starts when SM8034 is off.
- PWM output does not stop, even if a pulse stop command for positioning is driven.
- When specifying the number of output pulses, executing the DPWM instruction, and then outputting pulses again after the pulse output stops due to the completion of output of the specified number of pulses, turn OFF the contact which drove the DPWM instruction. When driving PWM output by the DHIOEN instruction, use the DHIOEN instruction to turn PWM output off.
- When the period setting is equivalent to the ON time setting, the output always remains ON. The output ON state continues even after "Period  $\times$  Number of output pulses" is finished in this condition.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1810H                      | The output destination specified by (d) is already used by another instruction (positioning instruction).<br>(The PWM output is not executed.)                               |
|                            | A Y device is specified as the output destination specified by (d), and there is no unused channel number in the parameter setting                                           |
| 2221H                      | The parameter set value is out of range.                                                                                                                                     |
| 3405H                      | Y10 or later is specified as the output destination specified by (d).<br>(The PWM output stops.)                                                                             |
| 3580H                      | An instruction that cannot be used in an interrupt program is used.                                                                                                          |
| 3600H                      | A channel number or a Y device that is not selected in the parameter setting are specified for the output destination specified by (d).<br>(The PWM output is not executed.) |
| 3611H(CH1)                 | The ON time specified by (s1) is larger than the period specified by (s2).<br>(The PWM output stops.)                                                                        |
| 3612H(CH2)                 |                                                                                                                                                                              |

# 8.19 Input Matrix Instruction

## Input matrix

### MTR

FX5S

FX5UJ

FX5U

FX5UC

Reads matrix input as 8-point input × "n"-point output (transistor) in the time division method.

\*1 Only X can be used.

\*2 Only Y can be used.

\*3 X cannot be used.

## Processing details

- An input signal of 8 points x "n" columns is controlled in the time division method using 8 inputs specified in (s) and transistor outputs specified in (d1). Each column is read in turn, and then output to devices specified in (d2).
- For each output, the I/O processing is executed immediately in turn in interrupt at every 10 ms or 20 ms.
- For the connection example of matrix input, refer to the following manual.

📖 MELSEC iQ-F FX5S/FX5UJ/FX5U/FX5UC User's Manual (Hardware)

- In this program example, n=Three outputs (Y20, Y21 and Y22) are set to ON in turn repeatedly. Every time an output is set to ON, eight inputs in the 1st, 2nd and 3rd columns are received in turn repeatedly, and stored to M30 to M37, M40 to M47 and M50 to M57 respectively. For wiring details, refer to the following manual.

📖 MELSEC iQ-F FX5S/FX5UJ/FX5U/FX5UC User's Manual (Hardware)

- The table below shows the related devices.

| Device | Name                           | Description                                                                                                                                            |
|--------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| SM8029 | Instruction execution complete | ON: Turns ON after the matrix in the nth (last) column is input.<br>OFF: Remains OFF while the matrix in the 1st to nth (last) columns is being input. |

## Precautions

- Eight devices are occupied from the device specified in (s).
- When specifying the output in (d2) , make sure that "n" output numbers specified in (d1) does not overlap the output specified in (d2).
- The MTR instruction can only be used once in a program.
- One diode of 0.1 A/50 V is required for each switch.
- Use the transistor output format.
- If write during RUN is executed while the MTR instruction is being executed, the control right is released by the END processing. The MTR instruction executed first in the next scan will acquire the control right next.
- For the MTR instruction, set the command input to normally Open.

- Normally, the following inputs should be used with the MTR instruction.
  - FX5S/FX5UJ CPU module: X10 and higher
  - FX5U/FX5UC CPU module: X20 and higher
- When using inputs other than those above, the receiving speed will be faster. However, the output transistor recovery time may be longer and the input sensitivity will be high, so there may be erroneous inputs. Change the input response time of unit parameter setting to "5 ms" to input at intervals of 10 ms. To prevent erroneous input pulses, connect pull-up resistors (3.3 kΩ/0.5 W) to transistor outputs used in MTR instruction. For pull-up resistors, use the power supply shown in the table below.

| Programmable controller   | Power supply used for pull-up resistors transistor output |
|---------------------------|-----------------------------------------------------------|
| AC power type CPU module. | Service power supply                                      |

**Ex.**

For FX5U-64MT/ES (sink input/sink output)

- Because 64 input points (8 rows × 8 columns) are received in a cycle of 80 or 160 ms, the ON/OFF duration of each input signal should be greater than or equal to the value shown below:

## Operation error

\*2 Only S can be used.  
\*3 T, ST, and C cannot be used.

### Processing details

- Specify the head input in the operation mode in (s).
- Selector switches in the operation mode occupy eight devices from the head device.

- The switch functions shown in the table below are assigned to each of the devices specified for selector switches in the operation mode. When X20 is assigned, it is necessary to set X20 to X24 as rotary switches so that they do not turn ON at the same time. It is not necessary to wire unused switches, but they cannot be used for any other purpose because they are occupied by IST instruction.

| Source | Device number (example) | Switch function      | Descriptions                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|-------------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (s)    | X20                     | Individual operation | Each load is turned ON and OFF by an individual pushbutton switch.                                                                                                                                                                                                                                                                                                                                                         |
| (s)+1  | X21                     | Return to zero point | When the pushbutton switch for zero return is pressed, the machine automatically returns to the zero point.                                                                                                                                                                                                                                                                                                                |
| (s)+2  | X22                     | Stepping             | Every time the start button is pressed, the machine performs one process.                                                                                                                                                                                                                                                                                                                                                  |
| (s)+3  | X23                     | Cycle operation      | When the start button is pressed while the machine is located at the zero point, the machine performs one cycle of automatic operation and stops at the zero point. If the stop button is pressed in the middle of one cycle, the machine stops immediately. When the start button is pressed after that, the machine performs the continuous operation from the last position, and automatically stops at the zero point. |
| (s)+4  | X24                     | Continuous operation | When the start button is pressed while the machine is located at the zero point, the machine starts continuous operation.<br>When the stop button is pressed, the machine finishes the current cycle until the zero point, and then stops at the zero point.                                                                                                                                                               |
| (s)+5  | X25                     | Zero return start    | Starts return to the zero point.                                                                                                                                                                                                                                                                                                                                                                                           |
| (s)+6  | X26                     | Automatic start      | Starts the stepping operation, cycle operation or continuous operation.                                                                                                                                                                                                                                                                                                                                                    |
| (s)+7  | X27                     | Stop                 | Stops each operation.                                                                                                                                                                                                                                                                                                                                                                                                      |

- Specify the smallest device number of practical state relays in (d1) (for the automatic mode).
- Specify the largest device number of practical state relays in (d2) (for the automatic mode).

- While the command input is ON, the following devices are automatically switched and controlled. While the command input is OFF, the devices are not switched.

| Device number | Descriptions             | ON/OFF condition |                                                                                                                                                                                                                                                    |

- Do not program the following state relays as general state relays;

| Device number | Descriptions                                                                                                                                                               | ON/OFF condition |                                                                                 |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|---------------------------------------------------------------------------------|
| S0 to S9      | Occupied for the initial state<br>• S0 to S2 are used for individual operation, zero return and automatic operation as shown above.<br>• S3 to S9 can be used arbitrarily. | ON condition     | Turns ON when a step relay (device S) is selected for the initial state.        |
|               |                                                                                                                                                                            | OFF condition    | Turns OFF when no step relay (device S) is selected.                            |
| S10 to S19    | Occupied for zero return                                                                                                                                                   | ON condition     | Turns ON when a step relay (device S) is selected for return to the zero point. |
|               |                                                                                                                                                                            | OFF condition    | Turns OFF when no step relay (device S) is selected.                            |

- If the devices are switched among individual operation (X20), zero return (X21) and automatic operation (X22, X23 and X24) while the zero return complete device (SM8043) is OFF, all outputs are set to OFF. Automatic operation can be started again after zero return is completed.

## Precautions

- It is not necessary to use all switches for mode selection. When some switches are not used, leave the corresponding numbers in the unused status. Such numbers cannot be used for any other purpose.
- The IST instruction should be programmed earlier than a series of STL circuit such as state relays S0 to S2.
- Use the state relays S10 to S19 for the zero return operation. In the final state in the zero return operation, set SM8043 to ON, and then let it be reset to OFF by itself.
- The IST instruction can only be used once in a program.

### ■IST instruction equivalent circuit

- The details on special relays (SM) and initial state relays (S0 to S9) which are automatically controlled by the IST instruction is as shown in the equivalent circuit below. (Refer to the equivalent circuit below for reference.) This equivalent circuit cannot be programmed.

SM8041 is set to ON when the start button is pressed in the automatic mode. Especially in the continuous mode, SM8041 holds its status by itself, and is reset when the stop button is pressed.

SM8040 is set to ON in the stepping mode, and set to OFF every time the start button is pressed. In the zero return operation or cycle operation, SM8040 holds its status by itself when the stop button is pressed, and is reset when the start button is pressed.

The initial state is switched according to each mode input, and SM8043 is controlled at the same time. However, it is necessary to control SM8044 and SM8043 in user programs also.

- When the operation mode is switched among the individual operation, zero return operation and automatic operation, all outputs and conventional states are reset at one time unless the machine is located in the zero point. (Reset of all outputs is not executed when SM8045 is driven.)

Even if the mode is switched from automatic operation to zero return operation while S2 is ON, state relays (except initial state relays) and outputs are not reset.

■Example of IST instruction introduction (example of workpiece transfer mechanism)

- Operation mode

| Operation mode |                             | Contents of operation                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Manual mode    | Individual operation mode:  | Each load is turned ON and OFF by an individual pushbutton switch.                                                                                                                                                                                                                                                                                                                                                            |
|                | Zero return operation mode: | When the pushbutton switch for zero return is pressed, the machine automatically returns to the zero point.                                                                                                                                                                                                                                                                                                                   |
| Automatic mode | Stepping operation mode:    | Every time the start button is pressed, the machine performs one process.                                                                                                                                                                                                                                                                                                                                                     |
|                | Cycle operation mode        | When the start button is pressed while the machine is located at the zero point, the machine performs one cycle of automatic operation and stops at the zero point.<br>If the stop button is pressed in the middle of one cycle, the machine stops immediately. When the start button is pressed after that, the machine performs the continuous operation from the last position, and automatically stops at the zero point. |
|                | Continuous operation mode   | When the start button is pressed while the machine is located at the zero point, the machine starts continuous operation.<br>When the stop button is pressed, the machine finishes the current cycle until the zero point, and then stops at the zero point.                                                                                                                                                                  |

- Transfer mechanism

- For using IST instruction, it is necessary to assign inputs having consecutive device numbers as shown below for mode inputs. When using non-consecutive inputs or omitting some modes, change the layout by using an auxiliary relay as the head input for mode specification as shown in the figure below.

| Input device | Assignment                 |
|--------------|----------------------------|
| X20          | Individual operation mode  |
| X21          | Zero return operation mode |
| X22          | Stepping operation mode    |
| X23          | Cycle operation mode       |
| X24          | Continuous operation mode  |
| X25          | Zero return start          |
| X26          | Automatic mode start       |
| X27          | Stop                       |

When inputs do not have consecutive device numbers

Example:  
X30: Individual operation mode  
X35: Zero return operation mode  
X33: Stepping operation mode  
X40: Cycle operation mode  
X32: Continuous operation mode  
X34: Zero return start  
X26: Automatic mode start  
X41: Stop

When only the continuous operation mode and zero return operation mode are used

Example:  
X30: Zero return operation mode  
X31: Continuous operation mode  
X32: Automatic mode start zero return start  
X33: Stop

When only the continuous operation mode and individual operation mode are used

Example:  
X30: Individual operation mode  
X31: Continuous operation mode  
X32: Automatic mode start  
X33: Stop

In this example, M0 is used as the head input for mode specification.

- Special relay (SM) used in the IST instruction are classified into two types. Some special relays are automatically controlled by the IST instruction itself according to the situation. Other special relays should be controlled by a program for preparation of operation or for purpose of control.

| Special relay                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Remarks                                                        |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| SM8040<br>(STL transfer disable)     | When this special relay turns ON, transfer of every state is disabled.<br>Individual operation mode: SM8040 is always effective.<br>Zero return operation mode and cycle operation mode: When the stop button is pressed, the operation is held until the start button is pressed.<br>Stepping operation mode: SM8040 is always effective except when the start button is pressed. When the start button is pressed, SM8040 is not effective and transfer of states is allowed.<br>Others: The operation is latched when the PLC mode switches from STOP to RUN, and reset when the start button is pressed. Even in the transfer disabled status, the operation is held for outputs in the states. | Special relays automatically controlled by the IST instruction |
| SM8041<br>(Transfer start)           | This special relay allows transfer from the initial state S2 to the next state.<br>Individual operation mode and zero return operation mode: SM8041 is not effective.<br>Stepping operation mode and cycle operation mode: SM8041 is effective only while the start button is pressed and held.<br>Continuous operation mode: The operation is latched when the start button is pressed, and cleared when the stop button is pressed.                                                                                                                                                                                                                                                               |                                                                |
| SM8042<br>(Start pulse)              | SM8042 is activated instantaneously only when the start button is pressed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                |
| SM8047<br>(Enable STL monitoring)    | When IST instruction is executed, SM8047 is set to ON.<br>When the SM8047 turns ON, STL monitoring becomes valid, and state relay numbers (S0 to S899) in the ON status are stored in turn in the ascending order of device number to the special register SD8040 to SD8047.<br>Up to eight state relay numbers in the ON status can be monitored.<br>If either state relay is ON, the special auxiliary relay SM8046 is set to ON.                                                                                                                                                                                                                                                                 |                                                                |
| SM8043<br>(Zero return complete)     | Set this special relay (SM) to ON by a user program when the machine returns to the zero point in the zero return operation mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Special relays controlled by a sequence program                |
| SM8044<br>(Zero point condition)     | Detect the zero point condition of the machine, and drive this special relay. This signal is effective in every mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                |
| SM8045<br>(All output reset disable) | When the mode is switched among individual operation mode, zero return operation mode and automatic mode, all outputs and operation state relays are reset if the machine is not located at the zero point. If SM8045 has been set to ON in advance, however, only operation state relays are reset.                                                                                                                                                                                                                                                                                                                                                                                                |                                                                |

## Program example

- While the machine is operating, the operation mode can be switched arbitrarily (among stepping operation, cycle operation and continuous operation) in the automatic mode. When the operation mode is switched between the individual operation mode, zero return operation mode and automatic mode while the machine is operating, all outputs are reset once to assure safety, after which the following mode becomes valid. (While SM8045 (All output reset disable) is ON, outputs are not reset at all.)

- Programming is not required when the individual operation mode is not provided.

- Programming is not required when the zero return operation mode is not provided. It is necessary to set SM8043 (zero return complete) to ON before starting the automatic mode.

- Automatic mode (stepping operation mode, cycle operation mode or continuous operation mode)

## Operation error

\*1 Only C can be used.

\*2 T, ST, and C cannot be used.

## Processing details

- In this example, outputs are controlled to on or off by one table rotation (0 to 360° using the rotation angle signal of 1°/pulse).
- The current value (s2) of the counter is compared with the data table with "n" lines starting from (s1) (which occupies "n" lines × 2 devices), and consecutive "n" outputs starting from (d) are controlled to on or off during one rotation.

- Write the following data to (s1) to (s1)+2(n)-1 in advance by a transfer instruction: For example, store 16-bit rising point data in even-numbered devices and 16-bit falling point data in odd-numbered devices.

| Rising point |                      | Falling point |                      | Target output |
|--------------|----------------------|---------------|----------------------|---------------|
| —            | Data value (example) | —             | Data value (example) |               |
| (s1)         | 40                   | (s1)+1        | 140                  | (d)           |
| (s1)+2       | 100                  | (s1)+3        | 200                  | (d)+1         |
| (s1)+4       | 160                  | (s1)+5        | 60                   | (d)+2         |
| (s1)+6       | 240                  | (s1)+7        | 280                  | (d)+3         |
| ⋮            | —                    | ⋮             | —                    | ⋮             |
| (s1)+2(n)-2  | —                    | (s1)+2(n)-1   | —                    | (d)+n-1       |

- The following figure shows the output patterns for device points (n) starting from (d) when the command input is set to on. Each rising point/falling point can be changed by overwriting the data in (s1) to (s1)+2(n)-1.

## Precautions

- When specifying the nibble of a bit device to (s1), specify a multiple of 16 (0, 16, 32, 64 ...) as a device number and always specify K4 for the number of digits.
- The value of (n) determines the number of target outputs ( $1 \leq (n) \leq 64$ ).
- Even if the command input is set to OFF, the ON/OFF status of outputs does not change.

## Operation error

| (s1)+13, (s1)+12         | 240                  | (s1)+15, (s1)+14         | 280                  | (d)+3         |
| ⋮                        | —                    | ⋮                        | —                    | ⋮             |
| (s1)+4(n)-3, (s1)+4(n)-4 | —                    | (s1)+4(n)-1, (s1)+4(n)-2 | —                    | (d)+n-1       |

- The following figure shows the output patterns for device points (n) starting from (d) when the command input is set to on. Each rising point/falling point can be changed by overwriting the data in (s1) to (s1)+2(n)-1.

## Precautions

- The DABSD instruction can specify a high-speed counter. When the high-speed counter is specified, the output pattern contains response delay caused by the scan cycle with regard to the current value of a counter.
- When specifying the nibble of a bit device to (s1), specify a multiple of 16 (0, 16, 32, 64 ...) as a device number and always specify K8 for the number of digits.
- The value of (n) determines the number of target outputs ( $1 \leq (n) \leq 64$ ).
- Even if the command input is set to OFF, the ON/OFF status of outputs does not change.

## Operation error

\*1 Only C can be used.

\*2 T, ST, and C cannot be used.

## Processing details

- The current value of a counter is compared with the data table having "n" lines starting from (s1) (which occupies "n" lines × 1 device). When the value is equivalent to the table data, the current output is reset, and the next output is controlled. In this way, the ON/OFF status of specified outputs is controlled in turn.

## ■ Operation example

- The following ladder example shows the operation. (s2) occupies two points. In the following timing chart, C0 and C1 correspond to the two points.

- Suppose that the following data is written in advance by a transfer instruction:

| Device storing data |                      | Output    |         |
|---------------------|----------------------|-----------|---------|
| —                   | Data value (example) | —         | Example |
| (s1)                | D300=20              | (d)       | M0      |
| (s1)+1              | D301=30              | (d)+1     | M1      |
| (s1)+2              | D302=10              | (d)+2     | M2      |
| (s1)+3              | D303=40              | (d)+3     | M3      |
| ⋮                   | ⋮                    | ⋮         | ⋮       |
| (s1)+(n)-1          | —                    | (d)+(n)-1 | —       |

- Timing chart

- When the command contact turns on, the output M0 turns on.
- When the current value of C0 reaches the comparison value D300, the output M0 is reset, "1" is added to the count value of the process counter C1, and the current value of the counter C0 is reset.
- The next output M1 turns ON.
- When the current value of C0 reaches the comparison value D301, the output M1 is reset, "1" is added to the count value of the process counter C1, and the current value of the counter C0 is reset.
- The current value is compared for up to "n (K4)" outputs in the same way ( $1 \leq (n) \leq 64$ ).
- When the final process specified by (n) is finished, the execution complete flag SM8029 turns on and remains on for one operation cycle. SM8029 is used for many instructions as the instruction execution complete flag. Use SM8029 as a contact just after a corresponding instruction.
- The program execution returns to the beginning, and outputs are repeated.

## Precautions

When specifying the nibble of a bit device to (s1), specify a multiple of 16 (0, 16, 32, 64 ...) as a device number.

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions calculate the addition data and horizontal parity value of data stored in (s) to (s)+(n)-1. The addition data is stored to (d), and the horizontal parity value is stored to (d)+1. The 16-bit mode and 8-bit mode are available for these instructions. For the operation in each mode, refer to the proceeding pages.

- 16-bit conversion mode (while SM8161 is OFF)

With regard to (n) data points starting from (s), the addition data and horizontal parity data of high-order 8 bits and low-order 8 bits are stored to (d) and (d)+1 respectively.

SM8161 is shared with the ASCII(P), HEXA(P), and CRC(P) instructions. SM8161 must always be off in the 16-bit mode.

SM8161 is cleared when the CPU module mode is changed from RUN to STOP.

In the following program, conversion is executed as follows:

| (s)                     | Example of data contents   |
|-------------------------|----------------------------|
| D100 lowest-order byte  | K100 = 0 1 1 0 0 1 0 0     |
| D100 highest-order byte | K111 = 0 1 1 0 1 1 1 (1) ← |
| D101 lowest-order byte  | K100 = 0 1 1 0 0 1 0 0     |
| D101 highest-order byte | K 98 = 0 1 1 0 0 0 1 0     |
| D102 lowest-order byte  | K123 = 0 1 1 1 1 0 1 (1) ← |
| D102 highest-order byte | K 66 = 0 1 0 0 0 0 1 0     |
| D103 lowest-order byte  | K100 = 0 1 1 0 0 1 0 0     |
| D103 highest-order byte | K 95 = 0 1 0 1 1 1 1 (1) ← |
| D104 lowest-order byte  | K210 = 1 1 0 1 0 0 1 0     |
| D104 highest-order byte | K 88 = 0 1 0 1 1 0 0 0     |
| Total                   | K1091                      |
| Horizontal parity       | 1 0 0 0 0 1 0 (1) ←        |

← When the number of "1" is odd, the horizontal parity is "1".  
When the number of "1" is even, the horizontal parity is "0".

D0    0   0   0   0   0   1   0   0   0   1   0   0   0   0   1   1   ← 1091 in BCD.

D1    0   0   0   0   0   0   0   0   1   0   0   0   0   1   0   1   ← Horizontal parity

- 8-bit conversion mode (while SM8161 is ON)
- With regard to (n) data points starting from (s), the addition data and horizontal parity data of only low-order 8 bits are stored to (d) and (d)+1 respectively. SM8161 is shared with the ASCI(P), HEXA(P), and CRC(P) instructions. SM8161 must always be on in the 8-bit mode. SM8161 is cleared when the CPU module mode is changed from RUN to STOP.
- In the following program, conversion is executed as follows:

| (s)               | Example of data contents   |
|-------------------|----------------------------|
| D100              | K100 = 0 1 1 0 0 1 0 0     |
| D101              | K111 = 0 1 1 0 1 1 1 (1) ← |
| D102              | K100 = 0 1 1 0 0 1 0 0     |
| D103              | K 98 = 0 1 1 0 0 0 1 0     |

#### Processing details

- These instructions search the same data as the 16-bit binary data of (s2) in (n) data starting from (s1), and store the search result in (d) to (d)+4.
- When the same data exists, five devices starting from (d) store the number of same data, first position, last position, maximum value position and minimum value position.
- When the same data does not exist, five devices starting from (d) store the number of same data, first position, last position, maximum value position and minimum value position. In this case, however, 0 is stored in three devices starting from (d) (which store the number of same data, first position and last position).

- The following table shows example of search result table configuration and data. (n=10)

| Searched device (s1) | Searched data (s1) value (example) | Comparison data (s2) value (example) | Data position | Search result       |                |                     |

| (s1)+8               | K210                               |                                      | 8             | ○                   |                |                     |
| (s1)+9               | K88                                |                                      | 9             |                     |                |                     |

- The following table shows example of search result table.

| Device number | Description | Search result item                     |
|---------------|-------------|----------------------------------------|
| (d)           | 3           | Number of same data                    |
| (d)+1         | 0           | Same data position (first position)    |
| (d)+2         | 6           | Same data position (last position)     |
| (d)+3         | 5           | Minimum value position (last position) |
| (d)+4         | 8           | Maximum value position (last position) |

## Precautions

- Comparison is executed algebraically. ( $-10 < 2$ )
- When there are two or more maximum or minimum values in the searched data, the last position of the max/min is stored respectively.
- When these instructions are driven, five devices ((d), (d)+1, (d)+2, (d)+3, and (d)+4) are occupied for storing the search result (d). Make sure that these devices are not used in other controls for the machine.

## Operation error

| Error code (SD0/SD8067) | Description                                                                       |
|-------------------------|-----------------------------------------------------------------------------------|
| 2820H                   | The device range specified by (s1) or (d) exceeds the corresponding device range. |
| 3405H                   | The value stored in a device specified by (n) is 0.                               |

## Processing details

- These instructions search the same data as the 32-bit binary data of (s2)+1 and (s2) in (n) data starting from (s1)+1 and (s1), and store the search result in (d)+1, (d) to (d)+9, and (d)+8.
- When the same data exists, five 32-bit binary data devices starting from (d)+1 and (d) store the number of same data, first position, last position, maximum value position and minimum value position.
- When the same data does not exist, five 32-bit binary data devices starting from (d)+1 and (d) store the number of same data, first position, last position, maximum value position and minimum value position. In this case, however, 0 is stored in three 32-bit devices starting from (d)+1 and (d) (which store the number of same data, first position and last position).

- The following table shows example of search result table configuration and data. (n=10)

| Searched device (s1) | Searched data (s1) value (example) | Comparison data (s2) value (example) | Data position | Search result              |                |                            |

| (s1)+19, (s1)+18     | K910000                            |                                      | 9             | ○                          |                |                            |

- The following table shows example of search result table.

| Device number | Description | Search result item                     |
|---------------|-------------|----------------------------------------|
| (d)+1, (d)    | 3           | Number of same data                    |
| (d)+3, (d)+2  | 0           | Same data position (first position)    |
| (d)+5, (d)+4  | 6           | Same data position (last position)     |
| (d)+7, (d)+6  | 5           | Minimum value position (last position) |
| (d)+9, (d)+8  | 9           | Maximum value position (last position) |

## Precautions

- Comparison is executed algebraically. ( $-10 < 2$ )
- When there are two or more maximum or minimum values in the searched data, the last position of the max/min is stored respectively.
- When these instructions are driven, five devices ( $[(d)+1, (d)]$ ,  $[(d)+3, (d)+2]$ ,  $[(d)+5, (d)+4]$ ,  $[(d)+7, (d)+6]$ , and  $[(d)+9, (d)+8]$ ) are occupied for storing the these result (d). Make sure that these devices are not used in other controls for the machine.

## Operation error

| Error code (SD0/SD8067) | Description                                                                       |

### Processing details

- These instructions store the total bits of 1 in the binary 16-bit data of the device specified by (s) to the device specified by (d).

The total of 1 is stored in the binary data. (In the example shown on the left, the total is 8.)

- When all binary 16-bit data of the device specified by (s) are 0 (off), the zero flag (SM8020) turns on.

### Precautions

While the command input is off, the instruction is not executed. The output of the number of bits in the on status is latched in the previous status.

## Program example

In the program example shown below, when X0 is ON, the number of bits in the ON status in D0 is counted, and stored to D2.

## Operation error

There is no operation error.

# Bit check of 32-bit data

## DSUM(P)

- FX5S
- FX5UJ
- FX5U
- FX5UC

These instructions store the total bits of 1 in the binary 32-bit data of the device specified by (s) to the device specified by (d).

## Processing details

- Diagram illustrating the bit structure of the  $(s)+1, (s)$  register. The register is 32 bits wide, with bits labeled b31 down to b0. The bits are grouped into two 16-bit sections: b31 to b16 and b15 to b0. The bits are divided into two groups: (s)+1 (bits b31 to b16) and (s) (bits b15 to b0). The bits are labeled as follows:
- | Bit   | b31 | b30 | b29 | ... | b17 | b16 | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|-------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| Value | 1   | 0   | 1   | ... | 1   | 1   | 1   | 0   | 1   | 0   | 0   | 0   | 0  | 1  | 0  | 1  | 0  | 0  | 1  | 1  | 1  | 1  |
| Key   | K31 | K30 | K29 | ... | K17 | K16 | K15 | K14 | K13 | K12 | K11 | K10 | K9 | K8 | K7 | K6 | K5 | K4 | K3 | K2 | K1 | K0 |
- The diagram also shows the bit positions for the  $(n)$  input. The  $(n)$  input is connected to bit b0 (K0) and bit b29 (K29). The bit positions for the  $(n)$  input are labeled as follows:
- $(n)=5$  (OFF)
  - $(n)=29$  (ON)

## Operation error

FX5UC

These instructions sort data lines in the data table (sorting source) having ((n1)×(n2)) points specified by (s) in the ascending order based on the group data in the column number (n3), and store the result in the data table (sorting result) having ((n1)×(n2)) points specified by (d).

## Processing details

- These instructions sort data lines in the data table (sorting source) having  $((n1) \times (n2))$  points specified by (s) in the ascending order based on the group data in the column number (n3), and store the result in the data table (sorting result) having  $(n1 \times n2)$  points specified by (d).
- The data table configuration is explained in an example in which the sorting source data table has 3 lines and 4 columns ( $n1 = K3$ ,  $n2 = K4$ ). For the sorting result data table, understand (s) as (d).

|                         |            | Number of groups (n2 = K4) |              |              |              |
|-------------------------|------------|----------------------------|--------------|--------------|--------------|
|                         |            | Column No. 1               | Column No. 2 | Column No. 3 | Column No. 4 |
|                         |            | Control number             | Height       | Weight       | Age          |
| Number of data (n1) = 3 | Line No. 1 | (s)                        | (s)+3        | (s)+6        | (s)+9        |
|                         | Line No. 2 | (s)+1                      | (s)+4        | (s)+7        | (s)+10       |
|                         | Line No. 3 | (s)+2                      | (s)+5        | (s)+8        | (s)+11       |

- When the command input turns on, data sorting is started. Data sorting is completed after (n1) scans, and the instruction execution complete flag SM8029 is set to on.
- The following table shows an operation example based on the sorting source data below. It is recommended to put a serial number such as a control number in the first column so that the original line number can be estimated based on the contents.

|                         |            | Number of groups (n2 = K4) |              |              |              |
|-------------------------|------------|----------------------------|--------------|--------------|--------------|
|                         |            | Column No. 1               | Column No. 2 | Column No. 3 | Column No. 4 |
|                         |            | Control number             | Height       | Weight       | Age          |
| Number of data (n1) = 5 | Line No. 1 | (s)                        | (s)+5        | (s)+10       | (s)+15       |
|                         |            | 1                          | 150          | 45           | 20           |

## Precautions

- Do not change the contents of operands and data during operation.
- To execute these instructions again, set the command input to off once, then on again.
- These instructions can only be used once in any program.
- When specifying the same device in (s) and (d), the source data is overwritten by the data acquired by sorting. Take special care so that the contents of (s) are not changed until execution is completed.

## Operation error

## Sorting 16-bit data 2

### SORTTBL2(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions sort data lines in the data table (sorting source) of 16-bit binary data having (n1×n2) points specified by (s) in the ascending order or descending order based on the group data in the column number (n3), and store the result in the data table (sorting result) of 16-bit binary data having ((n1)×(n2)) points specified by (d).

| Ladder diagram | Structured text                                                              |
|----------------|------------------------------------------------------------------------------|

## Processing details

- These instructions sort data lines in the data table (sorting source) of 16-bit binary data having (n1×n2) points specified by (s) in the ascending order or descending order based on the group data in the column number (n3), and store the result in the data table (sorting result) of 16-bit binary data having ((n1)×(n2)) points specified by (d).
- The data table configuration is explained in an example in which the sorting source data table has 3 lines and 4 columns (n1 = K3, n2 = K4). For the sorting result data table, understand (s) as (d).

|                         |            | Number of groups (n2 = K4) |              |              |              |
|-------------------------|------------|----------------------------|--------------|--------------|--------------|
|                         |            | Column No. 1               | Column No. 2 | Column No. 3 | Column No. 4 |
|                         |            | Control number             | Height       | Weight       | Age          |
| Number of data (n1) = 3 | Line No. 1 | (s)                        | (s)+1        | (s)+2        | (s)+3        |
|                         | Line No. 2 | (s)+4                      | (s)+5        | (s)+6        | (s)+7        |
|                         | Line No. 3 | (s)+8                      | (s)+9        | (s)+10       | (s)+11       |

- Set the sorting order by setting SM703 to on or off.

|             | Sorting order    |
|-------------|------------------|
| SM703 = ON  | Descending order |
| SM703 = OFF | Ascending order  |

- When the command input turns on, data sorting is started. Data sorting is completed after (n1) scans, and the instruction execution complete flag SM8029 is set to on.
- The following table shows an operation example based on the sorting source data below. It is recommended to put a serial number such as a control number in the first column so that the original line number can be estimated based on the contents.

|                         |            | Number of groups (n2 = K4) |              |              |              |
|-------------------------|------------|----------------------------|--------------|--------------|--------------|
|                         |            | Column No. 1               | Column No. 2 | Column No. 3 | Column No. 4 |
|                         |            | Control number             | Height       | Weight       | Age          |
| Number of data (n1) = 5 | Line No. 1 | (s)                        | (s)+1        | (s)+2        | (s)+3        |
|                         |            | 1                          | 150          | 45           | 20           |

## Precautions

- Do not change the contents of operands and data during operation.
- To execute these instructions again, set the command input to off once, then on again.
- These instructions can be used up to twice in any program.
- When specifying the same device in (s) and (d), the source data is overwritten by the data acquired by sorting. Take special care so that the contents of (s) are not changed until execution is completed.
- Ensure that the sorted data does not overlap with the source data.

## Operation error

| Error code (SD0/SD8067) | Description                                                               |
|-------------------------|---------------------------------------------------------------------------|
| 2820H                   | The device range specified by (s) exceeds the corresponding device range. |
|                         | The device range specified by (d) exceeds the corresponding device range. |

## Processing details

- These instructions sort data lines in the data table (sorting source) of 32-bit binary data having ( $n1 \times n2$ ) points specified by (s) in the ascending order or descending order based on the group data in the column number (n3), and store the result in the data table (sorting result) of 32-bit binary data having ( $(n1) \times (n2)$ ) points specified by (d).
- The data table configuration is explained in an example in which the sorting source data table has 3 lines and 4 columns ( $n1 = K3$ ,  $n2 = K4$ ). For the sorting result data table, understand (s) as (d).

|                         |            | Number of groups (n2 = K4) |                |                |                |
|-------------------------|------------|----------------------------|----------------|----------------|----------------|
|                         |            | Column No. 1               | Column No. 2   | Column No. 3   | Column No. 4   |
|                         |            | Control number             | Height         | Weight         | Age            |
| Number of data (n1) = 3 | Line No. 1 | (s)+1, (s)                 | (s)+3, (s)+2   | (s)+5, (s)+4   | (s)+7, (s)+6   |
|                         | Line No. 2 | (s)+9, (s)+8               | (s)+11, (s)+10 | (s)+13, (s)+12 | (s)+15, (s)+14 |
|                         | Line No. 3 | (s)+17, (s)+16             | (s)+19, (s)+18 | (s)+21, (s)+20 | (s)+23, (s)+22 |

- Set the sorting order by setting SM703 to on or off.

|             | Sorting order    |
|-------------|------------------|
| SM703 = ON  | Descending order |
| SM703 = OFF | Ascending order  |

- When the command input turns on, data sorting is started. Data sorting is completed after ( $n1$ ) scans, and the instruction execution complete flag SM8029 is set to on.
- The following table shows an operation example based on the sorting source data below. It is recommended to put a serial number such as a control number in the first column so that the original line number can be estimated based on the contents.

|                         |            | Number of groups (n2 = K4) |                |                |                |
|-------------------------|------------|----------------------------|----------------|----------------|----------------|
|                         |            | Column No. 1               | Column No. 2   | Column No. 3   | Column No. 4   |
|                         |            | Control number             | Height         | Weight         | Age            |
| Number of data (n1) = 5 | Line No. 1 | (s)+1, (s)                 | (s)+3, (s)+2   | (s)+5, (s)+4   | (s)+7, (s)+6   |
|                         |            | 1                          | 150            | 45             | 20             |

## Precautions

- Do not change the contents of operands and data during operation.
- To execute these instructions again, set the command input to off once, then on again.
- These instructions can be used up to or twice in any program.
- When specifying the same device in (s) and (d), the source data is overwritten by the data acquired by sorting. Take special care so that the contents of (s) are not changed until execution is completed.
- Ensure that the sorted data does not overlap with the source data.

## Operation error

| Error code (SD0/SD8067) | Description                                                               |
|-------------------------|---------------------------------------------------------------------------|
| 2820H                   | The device range specified by (s) exceeds the corresponding device range. |
|                         | The device range specified by (d) exceeds the corresponding device range. |
| 3405H                   | The value specified by (n1) is outside the following range.<br>1 to 32    |
|                         | The value specified by (n2) is outside the following range.<br>1 to 6     |
|                         | The value specified by (n3) is outside the following range.<br>1 to (n2)  |

# Adding 16-bit data

## WSUM(P)(\_U)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions add the (n) point(s) of 16-bit binary data in the device starting from the one specified by (s), and store the result in the device specified by (d).

| (d)     | DWSUM(P)            | —     | 64-bit signed binary   | ANY32_ARRAY       |
|         | DWSUM(P)_U          |       | 64-bit unsigned binary |                   |
| (n)     | Number of data      | —     | 16-bit unsigned binary | ANY16             |
| EN      | Execution condition | —     | Bit                    | BOOL              |
| ENO     | Execution result    | —     | Bit                    | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○                         | ○     | — | ○           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions add the (n) point(s) of 32-bit binary data in the device starting from the one specified by (s), and store the result in the device specified by (d).

## Precautions

In the 32-bit operation, the acquired sum is 64-bit data. The FX5 CPU module cannot handle 64-bit data. When the sum is within the numeric range of 32-bit data (K-2147483648 to K2147483647), however, the FX5 CPU module can handle the low-order 32 bits of 32-bit data as the sum while ignoring the high-order 32 bits.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------|
| 2820H                      | The device range specified by (d) exceeds the corresponding device range.                       |

|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions calculate the mean value of the (n) point(s) of 16-bit data starting from the one specified by (s), and store the operation result in a device specified by (d).

- The sum is obtained as algebraic sum, and divided by (n).
- The remainder is ignored.

### Precautions

When a device number is exceeded, (n) is handled as a smaller value in the possible range.

### Program example

In the program example shown below, the data of D0, D1 and D2 are summed, divided by "3", and then stored to D10.

### Operation error

| Error code<br>(SD0/SD8067) | Description                                         |
|----------------------------|-----------------------------------------------------|
| 3405H                      | The value stored in a device specified by (n) is 0. |

## Processing details

- These instructions calculate the square root of binary 16-bit data specified by (s1), and store the operation result in (d).

$$\sqrt{(s)} \rightarrow (d)$$

## Precautions

- The obtained square root is an integer because the decimal point is ignored. When the calculated decimal value is ignored, SM8021 (borrow flag) turns on.
- When the operation result is true 0, SM8020 (zero flag) turns on.

## Program example

In the program example shown below, the square root of D10 is stored to D12.

- When K100 is specified in D10

$$\begin{array}{ccc} D10 = K100 & & D12 = K10 \\ \sqrt{100} & \rightarrow & 10 \end{array}$$

## Processing details

- These instructions calculate the square root of binary 32-bit data specified by (s1), and store the operation result in (d).

$$\sqrt{(s)+1, (s)} \rightarrow (d)+1, (d)$$

## Precautions

- The obtained square root is an integer because the decimal point is ignored. When the calculated decimal value is ignored, SM8021 (borrow flag) turns on.
- When the operation result is true 0, SM8020 (zero flag) turns on.

# CRC calculation

## CRC(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions calculate the CRC (cyclic redundancy check) value which is an error check method used in communication. In addition to CRC value, parity check and sum check are available. For obtaining the horizontal parity value and sum check value, the CCD(P) instruction is available. For the generation of CRC value (CRC-16), these instructions use " $X^{16} + X^{15} + X^2 + 1$ " in a polynomial.

## Processing details

- These instructions generate CRC value for (n) 8-bit data (unit: byte) starting from a device specified in (s), and store to (d). The 16-bit conversion mode and 8-bit conversion mode are available for these instructions. For the operation in each mode, refer to the proceeding pages.

- 16-bit conversion mode (while SM8161 is OFF)

In this mode, the operation is executed for high-order 8 bits (1 byte) and low-order 8 bits (1 byte) of a device specified in (s). The operation result is stored to one 16-bit device specified in (d).

SM8161 is shared with the ASCI(P), HEXA(P), and CCD(P) instructions. SM8161 must always be off in the 16-bit mode.

In the following program, conversion is executed as follows:

|                                                          |             |                 | Example (s) = D100, (d) = D0, (n) = 6 |                         |         |
|----------------------------------------------------------|-------------|-----------------|---------------------------------------|-------------------------|---------|
|                                                          |             |                 | Device                                | Contents of target data |         |
|                                                          |             |                 |                                       | 8 bits                  | 16 bits |

|                                                          | ⋮           | ⋮               | —                                     |                         |         |
|                                                          | (s)+(n)/2-1 | Low-order byte  | —                                     |                         |         |
|                                                          |             | High-order byte |                                       |                         |         |
| Device storing the generated CRC value                   | (d)         | Low-order byte  | Low-order bits of D0                  | E4H                     | 41E4H   |
|                                                          |             | High-order byte | High-order bits of D0                 | 41H                     |         |

- 8-bit conversion mode (while SM8161 is ON)

In this mode, the operation is executed only for low-order 8 bits (low-order 1 byte) of a device specified by (s). With regard to the operation result, low-order 8 bits (1 byte) are stored to a device specified by (d), and high-order 8 bits (1 byte) are stored to a device specified by (d)+1.

SM8161 is shared with the ASCI(P), HEXA(P), and CCD(P) instructions. SM8161 must always be on in the 8-bit mode.

In the following program, conversion is executed as follows:

|                                                          |           |                 | Example (s) = D100, (d) = D0, (n) = 6 |                         |
|----------------------------------------------------------|-----------|-----------------|---------------------------------------|-------------------------|
|                                                          |           |                 | Device                                | Contents of target data |
| Device storing data for which the CRC value is generated | (s)       | Low-order byte  | Low-order bits of D100                | 01H                     |

|                                                          | (s)+5     | Low-order byte  | Low-order bits of D105                | 14H                     |
|                                                          | ⋮         |                 | —                                     |                         |
|                                                          | (s)+(n)-1 | Low-order byte  | —                                     |                         |
| Device storing the generated CRC value                   | (d)       | Low-order byte  | Low-order bits of D0                  | E4H                     |
|                                                          | (d)+1     | High-order byte | High-order bits of D0                 | 41H                     |

## Precautions

- In these instructions, " $X^{16}+X^{15}+X^2+1$ " is used in a polynomial for generating the CRC value (CRC-16). There are many other standard polynomials for generating the CRC value. Note that the CRC value completely differs if an adopted polynomial is different. Major polynomials for generating the CRC value are shown below.

| Name      | Polynomial                                                                                                    |
|-----------|---------------------------------------------------------------------------------------------------------------|
| CRC-12    | $X^{12} + X^{11} + X^3 + X^2 + X + 1$                                                                         |
| CRC-16    | $X^{16} + X^{15} + X^2 + 1$                                                                                   |

| CRC-CCITT | $X^{16} + X^{12} + X^5 + 1$                                                                                   |

## Program example

In the program example shown below, the CRC value of the data "0123456" stored in D100 to D106 is generated and stored to D0 when M0 turns ON.

- In the case of 16-bit conversion mode

|                                                      | Contents of data |                 |     |
|------------------------------------------------------|------------------|-----------------|-----|
|                                                      | Device           | Target data     |     |
| Device storing data for which CRC value is generated | D100: 3130H      | Low-order byte  | 30H |
|                                                      |                  | High-order byte | 31H |
|                                                      | D101: 3332H      | Low-order byte  | 32H |
|                                                      |                  | High-order byte | 33H |
|                                                      | D102: 3534H      | Low-order byte  | 34H |
|                                                      |                  | High-order byte | 35H |

|                                                      |                  |                 |     |

## Operation error

There is no operation error.

# 8.24 Indirect Address Read Instruction

## Reading the indirect address

### ADRSET(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions store the indirect address of the device specified by (s) to the device specified by (d).  
The addresses stored in the device specified by (d)+0 and (d)+1 are used by the program to execute the indirect address of the device.

| Ladder diagram | Structured text                               |
|----------------|-----------------------------------------------|
|                | ENO:=ADRSET(EN,s,d);<br>ENO:=ADRSETP(EN,s,d); |

| FBD/LD |
|--------|
|        |

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                                   | Range | Data type            | Data type (label) |
|---------|-------------------------------------------------------------------------------|-------|----------------------|-------------------|
| (s)     | Device number for reading the indirect address                                | —     | Device name          | ANY_ELEMENTARY*1  |
| (d)     | Device number for storing the indirect address of the device specified by (s) | —     | 32-bit signed binary | ANY32             |
| EN      | Execution condition                                                           | —     | Bit                  | BOOL              |
| ENO     | Execution result                                                              | —     | Bit                  | BOOL              |

\*1 Digit specified bit type label cannot be used.

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○*1                       | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions store the indirect address of the device specified by (s) to the device specified by (d). The addresses stored in the device specified by (d)+0 and (d)+1 are used by the program to execute the indirect address of the device.

- The nibble of a bit device, and the bit of a word device cannot be specified in (s).

## Precautions

- In the indirect specification, the device address used in sequence program is specified with a word device of 2 words (2-word devices). Use the indirect specification as an index when index register is insufficient.

- In the indirect specification, the device which specify the address of the specified device is specified by "@+(word device number)". For example, when "@D100" is specified, and the content of D101 and D100 becomes the device address.

## Operation error

There is no operation error.

## 8.25 Clock Instruction

### Reading clock data

#### TRD(P)

**FX5S****FX5UJ****FX5U****FX5UC**

These instructions read the clock data from the built-in real time clock in the CPU module.

| Ladder diagram                                                                    | Structured text                     |
|-----------------------------------------------------------------------------------|-------------------------------------|
|  | ENO:=TRD(EN,d);<br>ENO:=TRDP(EN,d); |
| FBD/LD                                                                            |                                     |
|  |                                     |

#### Setting data

| ENO     | Execution result                                       | —     | Bit                  | BOOL                                   |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (d)     | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |

#### Processing details

- These instructions read the clock data (SD210 to SD216) from the built-in real time clock in the CPU module to the device numbers (d) to (d)+6 in the following format.

| Special register |                      |                                  | Read data |                      |
|------------------|----------------------|----------------------------------|-----------|----------------------|
| Device           | Item                 | Clock data                       | Device    | Item                 |
| SD210            | Year                 | 1980 to 2079 (year, four digits) | (d)       | Year                 |
| SD211            | Month                | 1 to 12                          | (d)+1     | Month                |
| SD212            | Day                  | 1 to 31                          | (d)+2     | Day                  |
| SD213            | Hour data            | 0 to 23                          | (d)+3     | Hour data            |
| SD214            | Minute data          | 0 to 59                          | (d)+4     | Minute data          |
| SD215            | Second data          | 0 to 59                          | (d)+5     | Second data          |
| SD216            | Day-of-the-week data | 0 (Sunday) to 6 (Saturday)       | (d)+6     | Day-of-the-week data |

- The table below shows the related devices. The clock data stored in these special registers is updated during the END processing.

| Device                            | Name                                | Description                                                                                                   |
|-----------------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------|
| Binary code                       |                                     |                                                                                                               |
| SD210                             | Binary clock data (year)            | The year data in the clock data is stored as a four-digit binary code.                                        |
| SD211                             | Binary clock data (month)           | The month data in the clock data is stored as a binary code.                                                  |
| SD212                             | Binary clock data (day)             | The day data in the clock data is stored as a binary code.                                                    |
| SD213                             | Binary clock data (hour)            | The hour data in the clock data is stored as a binary code.                                                   |
| SD214                             | Binary clock data (minute)          | The minute data in the clock data is stored as a binary code.                                                 |
| SD215                             | Binary clock data (second)          | The second data in the clock data is stored as a binary code.                                                 |
| SD216                             | Binary clock data (day of the week) | The day-of-a-week data in the clock data (0: Sunday, 1: Monday, ..., 6: Saturday) is stored as a binary code. |
| Binary code (FX3 compatible area) |                                     |                                                                                                               |
| SD8013                            | Binary clock data (second)          | The second data in the clock data is stored as a binary code.                                                 |
| SD8014                            | Binary clock data (minute)          | The minute data in the clock data is stored as a binary code.                                                 |
| SD8015                            | Binary clock data (hour)            | The hour data in the clock data is stored as a binary code.                                                   |
| SD8016                            | Binary clock data (day)             | The day data in the clock data is stored as a binary code.                                                    |
| SD8017                            | Binary clock data (month)           | The month data in the clock data is stored as a binary code.                                                  |
| SD8018                            | Binary clock data (year)            | The year data in the clock data is stored as a four-digit binary code.                                        |
| SD8019                            | Binary clock data (day of the week) | The day-of-a-week data in the clock data (0: Sunday, 1: Monday, ..., 6: Saturday) is stored as a binary code. |

## Precautions

- These instructions occupy seven points of device starting from device number specified by (d). Make sure that these devices are not used by other machine controls.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| 2820H                      | The device range specified by (d) exceeds the corresponding device range. |

# Writing clock data

## TWR(P)

FX5S

FX5UJ

FX5U

FX5UC

This instruction writes the clock data to the built-in CPU module real time clock.

| Ladder diagram                                                                    | Structured text                     |

## Processing details

- These instructions write the clock data stored in device numbers (s) to (s)+6 to the clock data area (SD210 to SD216 and SD8013 to SD8019) of the built-in real time clock in the CPU module.

| Time setting data |                      |                                  | Special registers |                      |
|-------------------|----------------------|----------------------------------|-------------------|----------------------|
| Device            | Item                 | Clock data                       | Device            | Item                 |
| (s)               | Year                 | 1980 to 2079 (year, four digits) | SD210, SD8018     | Year                 |
| (s)+1             | Month                | 1 to 12                          | SD211, SD8017     | Month                |
| (s)+2             | Day                  | 1 to 31                          | SD212, SD8016     | Day                  |
| (s)+3             | Hour data            | 0 to 23                          | SD213, SD8015     | Hour data            |
| (s)+4             | Minute data          | 0 to 59                          | SD214, SD8014     | Minute data          |
| (s)+5             | Second data          | 0 to 59                          | SD215, SD8013     | Second data          |
| (s)+6             | Day-of-the-week data | 0 (Sunday) to 6 (Saturday)       | SD216, SD8019     | Day-of-the-week data |

- Executing these instructions immediately changes the real time clock data. Therefore, transfer the clock data of a few minutes ahead the current time to the clock data area (s) to (s)+6 in advance. Execute the instruction when the actual time matches the clock data time.
- When using these instructions to set the clock data (i.e., performing time adjustment), control of special relay SM8015 (clock stop/adjustment) is not required.
- If incorrect values (i.e., values out of range) are set to the write source area, the clock data will not be updated. In this case, correct the clock data in the write source area and execute the instruction.

- Day of the week (SD216 and SD8019) is automatically corrected.
- The table below shows the related devices.

| Device                            | Name                                | Description                                                                                                           |
|-----------------------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| SM8019                            | Real time clock error               | This special data register turns on when the clock data value in the special register is exceeding the setting range. |
| Binary code                       |                                     |                                                                                                                       |
| SD210                             | Binary clock data (year)            | The year data in the clock data is stored as a four-digit binary code.                                                |
| SD211                             | Binary clock data (month)           | The month data in the clock data is stored as a binary code.                                                          |
| SD212                             | Binary clock data (day)             | The day data in the clock data is stored as a binary code.                                                            |
| SD213                             | Binary clock data (hour)            | The hour data in the clock data is stored as a binary code.                                                           |
| SD214                             | Binary clock data (minute)          | The minute data in the clock data is stored as a binary code.                                                         |
| SD215                             | Binary clock data (second)          | The second data in the clock data is stored as a binary code.                                                         |
| SD216                             | Binary clock data (day of the week) | The day-of-a-week data in the clock data (0: Sunday, 1: Monday, ..., 6: Saturday) is stored as a binary code.         |
| Binary code (FX3 compatible area) |                                     |                                                                                                                       |
| SD8013                            | Binary clock data (second)          | The second data in the clock data is stored as a binary code.                                                         |
| SD8014                            | Binary clock data (minute)          | The minute data in the clock data is stored as a binary code.                                                         |
| SD8015                            | Binary clock data (hour)            | The hour data in the clock data is stored as a binary code.                                                           |
| SD8016                            | Binary clock data (day)             | The day data in the clock data is stored as a binary code.                                                            |
| SD8017                            | Binary clock data (month)           | The month data in the clock data is stored as a binary code.                                                          |
| SD8018                            | Binary clock data (year)            | The year data in the clock data is stored as a four-digit binary code.                                                |
| SD8019                            | Binary clock data (day of the week) | The day-of-a-week data in the clock data (0: Sunday, 1: Monday, ..., 6: Saturday) is stored as a binary code.         |

Precautions

- These instructions occupy seven points of device starting from device number specified by (s). Make sure that these devices are not used by other machine controls.

Program example

In the program example shown below, the CPU built-in real time clock is set (to 17:50:30 on Saturday, January 12, 2019).

- The shaded area indicates the set value of each item.
- When setting the time, it is recommended to set the time to several minutes ahead in advance, and then set X0 to ON when the accurate time is reached. The set time is then immediately written to the real time clock, and the clock data is updated.
- Every time X1 is set to ON, SM8017 is turned on and the current time can be corrected by ±30 seconds. For SM8017, refer to MELSEC iQ-F FX5 User's Manual (Application).

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| 2820H                      | The device range specified by (s) exceeds the corresponding device range. |

# Adding clock data

## TADD(P)

FX5S    FX5UJ    FX5U    FX5UC

These instructions add the time data stored in the device number specified by (s2) and later to the clock data stored in the device number specified by (s1) and later, and store the result to the device number specified by (d) and later.

| (s1)    | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions add the time data stored in the device numbers starting from (s2) to the clock data stored in the device numbers starting from (s1), and store the result to the device numbers starting from (d).

|        |        |           |   |        |        |           |   |       |        |           |
|--------|--------|-----------|---|--------|--------|-----------|---|-------|--------|-----------|
| (s1)   | hour   | (0 to 23) |   | (s2)   | hour   | (0 to 23) |   | (d)   | hour   | (0 to 23) |
| (s1)+1 | minute | (0 to 59) | + | (s2)+1 | minute | (0 to 59) | ⇒ | (d)+1 | minute | (0 to 59) |
| (s1)+2 | second | (0 to 59) |   | (s2)+2 | second | (0 to 59) |   | (d)+2 | second | (0 to 59) |

### Ex.

When adding 7:48:10 to 6:32:40

|        |    |   |        |    |   |       |    |
|--------|----|---|--------|----|---|-------|----|
| (s1)   | 6  |   | (s2)   | 7  |   | (d)   | 14 |
| (s1)+1 | 32 | + | (s2)+1 | 48 | ⇒ | (d)+1 | 20 |
| (s1)+2 | 40 |   | (s2)+2 | 10 |   | (d)+2 | 50 |

- If the sum of two values exceeds 24:00:00, the carry flag turns on, and the result will be the sum minus 24:00:00. For example, if a time value of 20:20:20 is added to another time value of 14:30:30, the sum is 34:40:50. However, the actual addition result will be 10:40:50.

|        |    |   |        |    |   |       |    |
|--------|----|---|--------|----|---|-------|----|
| (s1)   | 14 |   | (s2)   | 20 |   | (d)   | 10 |
| (s1)+1 | 20 | + | (s2)+1 | 20 | ⇒ | (d)+1 | 40 |
| (s1)+2 | 30 |   | (s2)+2 | 20 |   | (d)+2 | 50 |

- If the result is 0 (0:00:00), the zero flag turns on.
- If 1 second is added to 23:59:59, the result will be 0:00:00. This turns on both the carry flag and the zero flag.
- The table below shows the related devices.

| Device | Name  | Description                                                                                      |
|--------|-------|--------------------------------------------------------------------------------------------------|
| SM700  | Carry | If the result exceeds the maximum value of the time data, 23:59:59, this special relay turns on. |
| SM8020 | Zero  | If the result is 0:00:00, this special relay turns on.                                           |
| SM8022 | Carry | If the result exceeds the maximum value of the time data, 23:59:59, this special relay turns on. |

## Precautions

- These instructions occupy three points for each of three devices starting from device number specified by (s1), (s2), and (d) respectively. Make sure that these devices are not used by other machine controls.
- When using the time value (hour, minute, second) of the built-in real time clock in the CPU module for the operation, use the TRD(P) operation to read the special register values first. Then specify the word devices where the read values are stored to each operand.

## Program example

In the program shown below, when X0 is set to ON, the time obtained by adding the D20 to D22 time data to the D10 to D12 clock data is stored in D30 to D32.

|          |             |   |         |             |   |          |             |
|----------|-------------|---|---------|-------------|---|----------|-------------|
| D10      | 10 (hour)   |   | D20     | 3 (hour)    |   | D30      | 13 (hour)   |
| D11      | 30 (minute) | + | D21     | 10 (minute) | → | D31      | 40 (minute) |
| D12      | 10 (second) |   | D22     | 5 (second)  |   | D32      | 15 (second) |
| 10:30:10 |             |   | 3:10:05 |             |   | 13:40:15 |             |

- When the operation result exceeds 24 hours

|             |   |             |   |             |                      |
|-------------|---|-------------|---|-------------|----------------------|
| (s1)        |   | (s2)        |   | (d)         |                      |
| 18 (hour)   |   | 10 (hour)   |   | 4 (hour)    | ← 18 + 10 = 28 (≥24) |
| 10 (minute) | + | 20 (minute) | → | 30 (minute) |                      |
| 30 (second) |   | 5 (second)  |   | 35 (second) |                      |
| 18:10:30    |   | 10:20:05    |   | 4:30:35     |                      |

## Operation error

|                |                                                               |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                                         | Range | Data type            | Data type (label)                      |
|---------|-------------------------------------------------------------------------------------|-------|----------------------|----------------------------------------|
| (s1)    | Head device number where the clock data that is subtracted is stored                | —     | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| (s2)    | Head device number where the subtracting time value (or clock data value) is stored | —     | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| (d)     | Head device number where the resultant clock data (or time value) is stored         | —     | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| EN      | Execution condition                                                                 | —     | Bit                  | BOOL                                   |
| ENO     | Execution result                                                                    | —     | Bit                  | BOOL                                   |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s1)    | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions subtract the time data stored in the device numbers starting from (s2) from the clock data stored in the device numbers starting from (s1), and store the result to the device numbers starting from (d).

|        |        |           |        |        |           |       |        |           |
|--------|--------|-----------|--------|--------|-----------|-------|--------|-----------|
| (s1)   | hour   | (0 to 23) | (s2)   | hour   | (0 to 23) | (d)   | hour   | (0 to 23) |
| (s1)+1 | minute | (0 to 59) | (s2)+1 | minute | (0 to 59) | (d)+1 | minute | (0 to 59) |
| (s1)+2 | second | (0 to 59) | (s2)+2 | second | (0 to 59) | (d)+2 | second | (0 to 59) |

### Ex.

When subtracting 3:50:10 from 10:40:20

|        |    |        |    |       |    |
|--------|----|--------|----|-------|----|
| (s1)   | 10 | (s2)   | 3  | (d)   | 6  |
| (s1)+1 | 40 | (s2)+1 | 50 | (d)+1 | 50 |
| (s1)+2 | 20 | (s2)+2 | 10 | (d)+2 | 10 |

- If the remainder is a negative time value, the borrow flag turns on. The actual result will be the remainder plus 24:00:00. For example, if a time value of 10:42:12 is subtracted from another time value of 4:50:32, the remainder is -6:08:20. However, the actual subtraction result will be 18:08:20.

|        |    |        |    |       |    |
|--------|----|--------|----|-------|----|
| (s1)   | 4  | (s2)   | 10 | (d)   | 18 |
| (s1)+1 | 50 | (s2)+1 | 42 | (d)+1 | 8  |
| (s1)+2 | 32 | (s2)+2 | 12 | (d)+2 | 20 |

- If the result is 0 (0:00:00), the zero flag turns on.
- The table below shows the related devices.

| Device | Name   | Description                                                                                           |
|--------|--------|-------------------------------------------------------------------------------------------------------|
| SM8020 | Zero   | If the result is 0:00:00, this special relay turns on.                                                |
| SM8021 | Borrow | If the execution result of the TSUB(P) instruction is less than 0:00:00, this special relay turns on. |

## Precautions

- These instructions occupy three points for each of three devices starting from device number specified by (s1), (s2), and (d) respectively. Make sure that these devices are not used by other machine controls.
- When using the time value (hour, minute, second) of the built-in real time clock in the CPU module for the operation, use the TRD(P) operation to read the special register values first. Then specify the word devices where the read values are stored to each operand.

## Program example

In the program shown below, when X0 is set to ON, the time obtained by subtracting the D20 to D22 time data from the D10 to D12 clock data is stored in D30 to D32.

|                 |                 |                 |
|-----------------|-----------------|-----------------|
| D10 10 (hour)   | D20 3 (hour)    | D30 7 (hour)    |
| D11 30 (minute) | D21 10 (minute) | D31 20 (minute) |
| D12 10 (second) | D22 5 (second)  | D32 5 (second)  |
| 10:30:10        | 3:10:05         | 7:20:05         |

- When the operation result is smaller than "00:00:00"

|             |             |                               |
|-------------|-------------|-------------------------------|
| (s1)        | (s2)        | (d)                           |
| 5 (hour)    | 18 (hour)   | 11 (hour) ← 5 - 18 = -13 (<0) |
| 20 (minute) | 10 (minute) | 10 (minute)                   |
| 40 (second) | 5 (second)  | 35 (second)                   |
| 5:20:40     | 18:10:05    | 11:10:35                      |

## Operation error

# Converting time data from seconds to hour/minute/second in 32 bits

## DSTOH(P)

FX5S FX5UJ FX5U FX5UC

These instructions convert the 32-bit time value in seconds stored in the device numbers starting from (s) to the time value in the HHMMDD format, and store the converted data in the device numbers starting from (d).

| Ladder diagram                                                                    | Structured text                             |

### Processing details

- These instructions convert the time value in seconds stored in the device numbers starting from (s) to the time value in HHMMDD format, and store the converted data in the device numbers starting from (d).

#### Ex.

When specifying 45325 seconds in (s)

## Program example

In the program shown below, the time data in units of "second" stored in D0 and D1 is converted into data in units of "hour, minute, and second", and stored to D100, D101, and D102 when X20 turns ON.

- Converting the data in second into the data in hour, minute and second using DSTOH instruction (when "40000 seconds" is specified by D1 and D0)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                       |

## Processing details

- These instructions compare the date data in the devices specified by (s1) and (s2), or compare the date data in the device specified by (s1) with the current date. Set the comparison target by (s3).

- Comparing two specified date data

These instructions compare the date data in the device specified by (s1) with the date data in the device specified by (s2) in accordance with the conditions set by (s3). (Devices are used as a normally open contact.)

- Comparing the specified date data with the current date

These instructions compare the date data in the device specified by (s1) with the current date data in accordance with the conditions set by (s3). (Devices are used as a normally open contact.) The date data in the device specified by (s2) is regarded as dummy data and ignored.

- Set each data in binary.
- Set the 4 digit "year" data in the devices specified by (s1) and (s2) within the range 1980 to 2079.
- Set the "month" data in the devices specified by (s1)+1 and (s2)+1 within the range 1 to 12.
- Set the "date" data in the devices specified by (s1)+2 and (s2)+2 within the range 1 to 31.
- Set the following in (s3) as comparison target setting values. The following shows the bit configuration of (s3).

- (1) Set "day" as comparison target.
- (2) Set "month" as comparison target.
- (3) Set "year" as comparison target.
- (4) Set 0. If a value other than 0 is set, the operation result will be non-continuity.
- (5) When 1 is set to the 15 bit, the data in the device specified by (s1) is compared with the current date in accordance with the conditions set in the 0 to 2 bits.

- When 0 is set to the 0 to 2 bits, the date data are not compared. When 1 is set, the entire date data (year, month, and day) are compared.
- When 0 is set to the 15 bit, the data in the device specified by (s1) and the date data in the device specified by (s2) are compared. When 1 is set, the data in the device specified by (s1) is compared with the current date. The date data in the device specified by (s2) is ignored.
- The following table lists processing details of each bit.

| (s3) value when comparing two specified date data | (s3) value when comparing the specified date data with the current date | Comparison target | Contents of processing                                                                                                                          |
|---------------------------------------------------|-------------------------------------------------------------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001H                                             | 8001H                                                                   | Day               | Only data in the device specified by (s1)+2 is compared.                                                                                        |
| 0002H                                             | 8002H                                                                   | Month             | Only data in the device specified by (s1)+1 is compared.                                                                                        |
| 0003H                                             | 8003H                                                                   | Month, day        | Data in the device areas specified by (s1)+2 and (s1)+2 are compared.                                                                           |
| 0004H                                             | 8004H                                                                   | Year              | Only data in the device specified by (s1) is compared.                                                                                          |
| 0005H                                             | 8005H                                                                   | Year, day         | Data in the device areas specified by (s1) and (s1)+2 are compared.                                                                             |
| 0006H                                             | 8006H                                                                   | Year, month       | Data in the device areas specified by (s1) and (s1)+1 are compared.                                                                             |
| 0007H                                             | 8007H                                                                   | Year, month, day  | The entire date data in the device areas specified by (s1), (s1)+1, and (s1)+2 are compared.                                                    |
| Other than 0001H to 0007H, 8001H to 8007H         |                                                                         | None              | The entire date data in the device areas specified by (s1), (s1)+1, and (s1)+2 are not compared. (The operation result will be non-continuity.) |

- If the comparison target data in the device are not recognized as date data, SM709 turns on after the instruction is executed and the operation result will be non-continuity. Even if the data are not recognized as date data, SM709 does not turn on if the data are within the setting range. If the device areas specified by (s1) to (s1)+2 or (s2) to (s2)+2 exceed the corresponding device range, SM709 turns on after the instruction is executed and the operation result will be non-continuity as well. Once SM709 turns on, the on state is held until the CPU module is powered off or reset. Turn off SM 709 as needed.

- The following table lists the comparison operation results of each instruction.

| Instruction symbol | Condition | Result               |
|--------------------|-----------|----------------------|
| DT=                | (s1)=(s2) | Conductive state     |
| DT<>               | (s1)≠(s2) |                      |
| DT>                | (s1)>(s2) |                      |
| DT<=               | (s1)≤(s2) |                      |
| DT<                | (s1)<(s2) |                      |
| DT>=               | (s1)≥(s2) |                      |
| DT=                | (s1)≠(s2) | Non-conductive state |
| DT<>               | (s1)=(s2) |                      |
| DT>                | (s1)≤(s2) |                      |
| DT<=               | (s1)>(s2) |                      |
| DT<                | (s1)≥(s2) |                      |
| DT>=               | (s1)<(s2) |                      |

#### Ex.

The date data A, B, and C are compared.

- The following table lists the comparison operation results between A, B, and C. Even when the data are compared under the same conditions, the results differ depending on the comparison target data.

○: Continuity, ×: Non-continuity

| Comparison target data | Condition |     |     |
|------------------------|-----------|-----|-----|
|                        | A<B       | B<C | A<C |
| Day                    | ○         | ×   | ×   |
| Month                  | ×         | ○   | ×   |
| Month, day             | ×         | ○   | ×   |
| Year                   | ○         | ○   | ○   |
| Year, day              | ○         | ○   | ○   |
| Year, month            | ○         | ○   | ○   |
| Year, month, day       | ○         | ○   | ○   |
| None                   | ×         | ×   | ×   |

- Even though the specified date does not exist, the comparison operation is performed in accordance with the conditions in the following table as long as the date data are within the valid range.

- Date A: 2006/02/30 (Even though the date does not exist, this date can be set.)
- Date B: 2007/03/29
- Date C: 2008/02/31 (Even though the date does not exist, this date can be set.)

○: Continuity, ×: Non-continuity

| Comparison target data | Condition |     |     |
|------------------------|-----------|-----|-----|
|                        | A<B       | B<C | A<C |
| Day                    | ×         | ×   | ○   |
| Month                  | ×         | ×   | ×   |
| Month, day             | ○         | ×   | ○   |
| Year                   | ○         | ○   | ○   |
| Year, day              | ○         | ○   | ○   |
| Year, month            | ○         | ○   | ○   |
| Year, month, day       | ○         | ○   | ○   |
| None                   | ×         | ×   | ×   |

These instructions compare the time data in the devices specified by (s1) and (s2). Or, these instructions compare the time data in the device specified by (s1) with the current time.

Set the comparison target by (s3).

| Ladder diagram                                                        | Structured text <sup>*1</sup>                                                                                                                         |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>( "=", "&lt;&gt;", "&gt;", "&lt;=", "&lt;", "&gt;=" enters □.)</p> | <pre>ENO:=LDTM_□(EN,s1,s2,s3); ENO:=ANDTM_□(EN,s1,s2,s3); ENO:=ORTM_□(EN,s1,s2,s3); ("EQ", "NE", "GT", "LE", "LT", "GE" enters □.)*<sup>2</sup></pre> |

### FBD/LD

\*1 Supported by engineering tool version "1.035M" and later.

\*2 EQ is =, NE is <>, GT is >, LE is <=, LT is <, and GE is >=.

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                             | Range                          | Data type            | Data type (label) |
|---------|-------------------------------------------------------------------------|--------------------------------|----------------------|-------------------|
| (s1)    | Head device number where the comparison data is stored                  | —                              | 16-bit signed binary | ANY_TM            |

## Processing details

- These instructions compare the time data in the devices specified by (s1) and (s2), or compare the time data in the device specified by (s1) with the current time. Set the comparison target by (s3).

- Comparing two specified time data

These instructions compare the time data in the device specified by (s1) with the time data in the device specified by (s2) in accordance with the conditions set by (s3). (Devices are used as a normally open contact.)

- Comparing specified time data with current time data

These instructions compare the time data in the device specified by (s1) with the current time data in accordance with the conditions set by (s3). (Devices are used as a normally open contact.) The time data in the device specified by (s2) is regarded as dummy data and ignored.

- Set each data in binary.
- Set the "hour" data as in the 24-hour clock in the devices specified by (s1) and (s2) within the range 0 to 23.
- Set the "minute" data in the devices specified by (s1)+1 and (s2)+1 within the range 0 to 59.
- Set the "second" data in the devices specified by (s1)+2 and (s2)+2 within the range 0 to 59.
- Set the following in (s3) as comparison target setting values. The following shows the bit configuration of (s3).

- (1) Set "second" as comparison target.
- (2) Set "minute" as comparison target.
- (3) Set "hour" as comparison target.
- (4) Set 0. If a value other than 0 is set, the operation result will be non-continuity.
- (5) When 1 is set to the 15 bit, the data in the device specified by (s1) is compared with the current time in accordance with the conditions set in the 0 to 2 bits.

- When 0 is set to the 0 to 2 bits, the time data (hour, minute, and second) are not compared. When 1 is set, the entire time data (hour, minute, and second) are compared.
- When 0 is set to the 15 bit, the data in the device specified by (s1) and the time data in the device specified by (s2) are compared. When 1 is set, the data in the device specified by (s1) is compared with the current time. The time data in the device specified by (s2) is ignored.
- The following table lists processing details of each bit.

| (s3) value when comparing two specified time data | (s3) value when comparing the specified time data with the current time | Comparison target             | Contents of processing                                                                                                                          |
|---------------------------------------------------|-------------------------------------------------------------------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001H                                             | 8001H                                                                   | Second data                   | Only data in the device specified by (s1)+2 is compared.                                                                                        |
| 0002H                                             | 8002H                                                                   | Minute data                   | Only data in the device specified by (s1)+1 is compared.                                                                                        |
| 0003H                                             | 8003H                                                                   | Minute and second data        | Data in the device areas specified by (s1)+2 and (s1)+1 are compared.                                                                           |
| 0004H                                             | 8004H                                                                   | Hour data                     | Only data in the device specified by (s1) is compared.                                                                                          |
| 0005H                                             | 8005H                                                                   | Hour and second data          | Data in the device areas specified by (s1) and (s1)+2 are compared.                                                                             |
| 0006H                                             | 8006H                                                                   | Hour and minute data          | Data in the device areas specified by (s1) and (s1)+1 are compared.                                                                             |
| 0007H                                             | 8007H                                                                   | Hour, minute, and second data | The entire time data in the device areas specified by (s1), (s1)+1, and (s1)+2 are compared.                                                    |
| Other than 0001H to 0007H, 8001H to 8007H         |                                                                         | None                          | The entire time data in the device areas specified by (s1), (s1)+1, and (s1)+2 are not compared. (The operation result will be non-continuity.) |

- If the comparison target data in the device are not recognized as time data, SM709 turns on after the instruction is executed and the operation result will be non-continuity. If the device areas specified by (s1) to (s1)+2 or (s2) to (s2)+2 exceed the corresponding device range, SM709 turns on after the instruction is executed and the operation result will be non-continuity as well. Once SM709 turns on, the on state is held until the CPU module is powered off or reset. Turn off SM709 as needed.

- The following table lists the comparison operation results of each instruction.

| Instruction symbol | Condition | Result               |
|--------------------|-----------|----------------------|
| TM=                | (s1)=(s2) | Conductive state     |
| TM<>               | (s1)≠(s2) |                      |
| TM>                | (s1)>(s2) |                      |
| TM<=               | (s1)≤(s2) |                      |
| TM<                | (s1)<(s2) |                      |
| TM>=               | (s1)≥(s2) |                      |
| TM=                | (s1)≠(s2) | Non-conductive state |
| TM<>               | (s1)=(s2) |                      |
| TM>                | (s1)≤(s2) |                      |
| TM<=               | (s1)>(s2) |                      |
| TM<                | (s1)≥(s2) |                      |
| TM>=               | (s1)<(s2) |                      |

#### Ex.

The time data A, B, and C are compared.

- The following table lists the comparison operation results between A, B, and C. Even when the data are compared under the same conditions, the results differ depending on the comparison target data.

○: Continuity, ×: Non-continuity

| Comparison target data        | Condition |     |     |
|-------------------------------|-----------|-----|-----|
|                               | A<B       | B<C | A<C |
| Second data                   | ○         | ×   | ×   |
| Minute data                   | ×         | ○   | ×   |
| Minute and second data        | ×         | ○   | ×   |
| Hour data                     | ○         | ○   | ○   |
| Hour and second data          | ○         | ○   | ○   |
| Hour and minute data          | ○         | ○   | ○   |
| Hour, minute, and second data | ○         | ○   | ○   |
| None                          | ×         | ×   | ×   |

#### Operation error

There is no operation error.

# Comparing clock data

## TCMP(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions compare the time specified by (s1), (s2), and (s3) with the time data specified by (s4), and turn on/off the bit device specified by (d) depending on the size match.

| Ladder diagram | Structured text                                                       |

| (s3)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (s4)    | —                           | ○                         | ○     | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | ○                           | ○*1                       | —     | — | —           | —  | —                      | —        | — | —  | —      |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions compare the time specified by (s1), (s2), and (s3) with the time data specified by (s4), and turn on/off the bit device specified by (d) depending on the size match.

- (d), (d)+1, and (d)+2 hold the state before the command contact is turned off even if, the TCMP instruction is not executed by switching on  $\rightarrow$  off the command contact.

## Precautions

- Three devices are occupied by (s4) and (d). Make sure that these devices are not used by other machine controls.
- Specify each operand of the word device after reading the value of the special register used in the TRD(P) instruction when the time (hour, minute, second) of the clock data of the built-in real time clock in the CPU module is used.

## Program example

In the program shown below, when X0 is set to ON, the time (10 hours 30 minutes 50 seconds) designated with (s1) to (s3) is compared with the D0 to D2 clock data, and the results are stored in M0 to M2.

# Comparing clock data zones

## TZCP(P)

FX5S

FX5UJ

FX5U

FX5UC

This instruction compares two comparison time (comparison time zone) specified by (s1) and (s2) with the time data specified by (s3), and turns on or off the specified bit devices (d) according to the comparison results.

| Ladder diagram | Structured text                                                 |

\*1 T, ST, and C cannot be used.

## Processing details

- This instruction compares two comparison time (comparison time zone) specified by (s1) and (s2) with the time data specified by (s3), and turns on or off the specified bit devices (d) according to the comparison results.

- Even if the command contact turns off from on and the TZCP instruction is not executed, (d), (d)+1, and (d)+2 hold the status before the command contact turned off.

## Precautions

- Three devices are occupied by (s1), (s2), (s3), and (d). Make sure that these devices are not used by other machine controls.
- When the time (hour, minute, second) of the clock data of the real time clock built in the CPU module is used, read the values of special registers by the TRD instruction, and then specify those word devices as the operands.
- Make (s1)  $\leq$  (s2).

## Program example

In the program shown below, when X0 is set to ON, the range of the D20 to D22 and D30 to D32 clock data is compared with the D0 to D2 clock data, and the results are stored in M3 to M5.

(s1), (s1)+1, (s1)+2: Specify the lower limit of the comparison time zone in "hour", "minute" and "second."

(s2), (s2)+1, (s2)+2: Specify the upper limit of the comparison time zone in "hour", "minute" and "second."

(s3), (s3)+1, (s3)+2: Specify the time data in "hour", "minute" and "second."

(d), (d)+1, (d)+2: Turn ON or OFF according to the comparison result.

The setting range of "hour" is from 0 to 23.

The setting range of "minute" is from 0 to 59.

The setting range of "second" is from 0 to 59.

## Operation error

\*1 Only SM can be used.

## Processing details

- This instruction sets user timing clock output destinations (SM420 to SM424 and SM8330 to SM8334) specified by (d) to on for the number of scans specified by (n1) and to off for the number of scans specified by (n2).

(n1): (n1) scans

(n2): (n2) scans

- Specify SM420 to SM424 (SM8330 to SM8334) in the special relay of the timing clock output destination specified by (d).
- In SM420 to SM424 (SM8330 to SM8334), when one device is turned on, another device is also turned on at the same time.
- The counted number of scans is stored among SD8330 to SD8334 in accordance with the special relay of the timing clock output destination specified by (d).
- The counted number of scans stored among SD8330 to SD8334 is reset when the counted value reaches "(n1)+(n2)" or when the command input (instruction) is set to on.

| Special relay (d) for outputting the timing clock | Scan counting device |
|---------------------------------------------------|----------------------|
| SM420(SM8330)                                     | SD8330               |
| SM421(SM8331)                                     | SD8331               |
| SM422(SM8332)                                     | SD8332               |
| SM423(SM8333)                                     | SD8333               |
| SM424(SM8334)                                     | SD8334               |

- When the command input is set to ON, the operation is started. The special relay of the timing clock output destination is set to ON or OFF by the END instruction. Even if the command input is set to OFF, the operation is not stopped. In the STOP mode, the operation is stopped. When the power to the CPU module is turned OFF, the operation is stopped.
- When (n1) and (n2) are set to "0", the status is as shown below:

| Status of (n1) and (n2) | ON/OFF status of (d) |
|-------------------------|----------------------|
| (n1)=0, (n2)≥0          | (d)= Fixed to OFF    |
| (n1)>0, (n2)=0          | (d)= Fixed to ON     |

- The table below shows the related devices (special relay).

| Special relay | Name                  | Description                                 |
|---------------|-----------------------|---------------------------------------------|
| SM420(SM8330) | Timing clock output 1 | Timing clock output in the DUTY instruction |
| SM421(SM8331) | Timing clock output 2 |                                             |
| SM422(SM8332) | Timing clock output 3 |                                             |
| SM423(SM8333) | Timing clock output 4 |                                             |
| SM424(SM8334) | Timing clock output 5 |                                             |

- The table below shows the related devices (special register).

| Special register | Name                                              | Description                                                               |
|------------------|---------------------------------------------------|---------------------------------------------------------------------------|
| SD8330           | Counted number of scans for timing clock output 1 | Counted number of scans for timing clock output 1 in the DUTY instruction |
| SD8331           | Counted number of scans for timing clock output 2 | Counted number of scans for timing clock output 2 in the DUTY instruction |
| SD8332           | Counted number of scans for timing clock output 3 | Counted number of scans for timing clock output 3 in the DUTY instruction |
| SD8333           | Counted number of scans for timing clock output 4 | Counted number of scans for timing clock output 4 in the DUTY instruction |
| SD8334           | Counted number of scans for timing clock output 5 | Counted number of scans for timing clock output 5 in the DUTY instruction |

## Precautions

- The DUTY instruction can be used up to 5 times (points). It is not permitted, however, to use the same timing clock output destination device for two or more DUTY instructions.

## Program example

In the program shown below, when X0 is set to ON, SM420 is set to ON for 1 scan, and is set to OFF for 3 scans.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------|
| 2820H                      | The device specified by (d) is out of the range from SM420 to SM424 (SM8330 to SM8334). |
| 3405H                      | The value specified by (n1), (n2) is other than 0 to 32767.                             |

# Hour meter

## HOURLM

FX5S

FX5UJ

FX5U

FX5UC

This instruction measures the on time of the input contact in units of hour.

| Ladder diagram                                                                    | Structured text          |

\*1 T, ST, and C cannot be used.

### Processing details

- This instruction measures the period of time for which the input contact is on in units of hour, and turns on the device specified by (d2) when the accumulated ON time exceeds the time (16-bit binary data) specified in (s).
- In (s), specify the period of time until the device specified by (d2) is turned on in units of hour.
- The measured current value in units of hour is stored in (d1).
- The measured current value of less than one hour (in units of second) is stored in (d1)+1.
- (d2) is set to on when the current value in (d1) exceeds the time specified by (s).
- Specify a latched (battery backed) type data register as (d1) so that the current value data can be continuously used even after the power to CPU module turns off. If a general data type register is used, the current value data is cleared when the power to the CPU module is turned OFF or when the controller mode switches from STOP to RUN.
- Even after the alarm output specified by (d2) turns ON, the measurement is continued.
- When the current value reaches the maximum value of 16-bit data, the measurement is stopped. For continuing the measurement, clear the current value stored in (d1) to (d1)+1.

## Precautions

- Two devices are occupied by (d1). Make sure that these devices are not used by other machine controls.

## Program example

In the program example shown below, when the accumulated X0 ON time exceeds 300 hours, Y5 turns ON. The current value less than one hour is stored in D201 in units of second.

- (s) : Time after which (d2) is set to ON  
Specify a value in units of hour.
- (d1) : Current value in units of hour
- (d1)+1 : Current value less than one hour (unit: second)
- (d2) : Alarm output destination  
Turns ON when the current value (d1) reaches or exceeds the time specified in (s).  
(In this example, the alarm output destination turns ON when the current value becomes 300 hours.)

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

- This instruction measures the period of time for which the input contact is on in units of hour, and turns on the device specified by (d2) when the accumulated ON time exceeds the time (32-bit binary data) specified in (s).
- In (s)+1 and (s), specify the period of time until the device specified by (d2) is turned on in units of hour.
- The measured current value in units of hour is stored in (d1)+1 and (d1). ((d1)+1: highest-order, (d1): lowest-order)
- The measured current value of less than one hour (in units of second) is stored in (d1)+2.
- (d2) is set to on when the current value in (d1)+1 and (d1) exceeds the time specified by (s).
- Specify a latched (battery backed) type data register as (d1) so that the current value data can be continuously used even after the power to CPU module turns off. If a general data type register is used, the current value data is cleared when the power to the CPU module is turned OFF or when the controller mode switches from STOP to RUN.
- Even after the alarm output specified by (d2) turns ON, the measurement is continued.
- When the current value reaches the maximum value of 32-bit data, the measurement is stopped. For continuing the measurement, clear the current value stored in (d1) to (d1)+2.

## Precautions

- Three devices are occupied by (d1). Make sure that these devices are not used by other machine controls.

\*1 Only X and Y can be used.

## Processing details

- This function refreshes only the corresponding devices in the middle of a scan and receives an external input or generates an output.
- Since the input receptions and external outputs are performed at one time only after the END instruction is executed in the program, a pulse signal cannot be output externally in the middle of a scan. The execution of the I/O refresh instruction forcibly refreshes the corresponding input (X) or output (Y) in the middle of program execution, and then a pulse signal can be output externally in the middle of a scan.
- To refresh an input (X) or an output (Y) in 1 point units, use the direct access input (DX) or the direct access output (DY).

### Ex.

When a program using the RFS instruction is changed to a program using direct access input/output

(1): Refreshes X0.

(2): Refreshes Y20.

## Program example

In the program example shown below, when X0 is set to ON, X10 to X17 (8 points in total) are refreshed.

In the program example shown below, when X1 is set to ON, Y0 to Y7, Y10 to Y17 and Y20 to Y27 (24 points in total) are refreshed.

## Operation error

| (n)     | ○                           | ○                         | ○     | ○ | —           | —   | ○                      | ○        | — | —  | —          |

\*1 Only the DFROM(P) instruction can be used.

## Processing details

### FROM(P)

- These instructions read (n) words of data from the buffer memory specified by (s) in intelligent function module specified by (U/H), and store the data to the device specified by (d) and later.

### DFROM(P)

- These instructions read the  $(n) \times 2$  words of data from the buffer memory specified by (s) in intelligent function module specified by (U/H), and store the data to the device specified by (d) and later.

## Precautions

- For the nibble of a bit device specified by (d), specify K1 to K4 in the FROM(P) instruction and K1 to K8 in the DFROM(P) instruction.
- When a number greater than 65535 is specified as the buffer memory specified by (s), use the FROMD(P) instruction or use  $U\Box\backslash G\Box$  in the MOV(P) instruction. The following shows the program to transfer the buffer memory #70000 in the intelligent function module No. 1 to D0.

## Program example

When the buffer memory #4 of the module No. 1 is read to D0.

When the buffer memories #0 to #3 of the module No. 1 are read to D10 to D13.

## Operation error

| 3060H                      | Signal error is detected while accessing the connected units during the execution of the instruction.                      |
| 3580H                      | An instruction that cannot be used in an interrupt program is used.                                                        |

**Common items among the FROM(P), DFROM(P), TO(P), and DTO(P) (details)**

- Use the module number to specify which Intelligent function module the instruction works for. The setting range of each CPU module is shown below.
  - FX5UJ CPU module: 1H to 8H (K1 to K8)
  - FX5U/FX5UC CPU module: 1H to 10H (K1 to K16)

|            |            | Module No. 1                |                             | Module No. 2                |            | Module No. 3                | Module No. 4          | Module No. 5                |
|------------|------------|-----------------------------|-----------------------------|-----------------------------|------------|-----------------------------|-----------------------|-----------------------------|
| CPU module | I/O module | Intelligent function module | Extension power supply unit | Intelligent function module | I/O module | Intelligent function module | Bus conversion module | Intelligent function module |

- A module number is automatically assigned to each intelligent function module connected to a CPU module. The module number is assigned in the way "No. 1 → No. 2 → No. 3 ..." starting from the equipment nearest the CPU module.
- 16-bit RAM memories are built in an intelligent function module, and they are called buffer memories. The contents of buffer memories vary depending on the purpose of control of each Intelligent function module, and the setting range is from K0 to K65535.
- The number of read data is specified by (n), and the setting range is from K1 to K65535.

- If this instruction is executed in an interrupt program with the priority 1, operation error (3580H) occurs. This instruction operates in an interrupt program with the priority 2 or 3.
- If this instruction is executed to an FX3 intelligent function module within an interrupt program, operation error (3580H) occurs.

# Writing 1-word/2-word data to another module

## TO(P), DTO(P)

FX5S

FX5UJ

FX5U

FX5UC

### • TO(P)

These instructions write the (n) points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

### • DTO(P)

These instructions write the (n) × 2 points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

\*1 Only the DTO(P) instruction can be used.

## Processing details

### ■TO(P)

- These instructions write the (n) points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

- When a constant is specified in (s2), (n) words of the same data (the value specified by (s2)) is written starting from the specified buffer memory address.

## ■ DTO(P)

- These instructions write the  $(n) \times 2$  points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

- When a constant is specified in (s2),  $(n) \times 2$  words of the same data (the value specified by (s2)) is written starting from the specified buffer memory address.

## Precautions

- For the nibble of a bit device specified by (s2), specify K1 to K4 in the TO(P) instruction and K1 to K8 in the DTO(P) instruction.
- When a number greater than 65535 is specified as the buffer memory specified by (s1), use the TOD(P) instruction or use  $U \square \setminus G \square$  in the MOV(P) instruction.

## Program example

When writing "0" to the buffer memory #27 of the module No. 1.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                                                                                                               |

\*1 Only the DFROMD(P) instruction can be used.

## Processing details

### ■FROMD(P)

- These instructions read (n) words of data from the buffer memory specified by (s) in intelligent function module specified by (U/H), and store the data to the device specified by (d) and later.

### ■DFROMD(P)

- These instructions read the  $(n) \times 2$  words of data from the buffer memory specified by (s) in intelligent function module specified by (U/H), and store the data to the device specified by (d) and later.

## Precautions

- For the nibble of a bit device specified by (d), specify K1 to K4 in the FROMD(P) instruction and K1 to K8 in the DFROMD(P) instruction.

**Common items among the FROMD(P), DFROMD(P), TOD(P), and DTOD(P) (details)**

- Use the module number to specify which intelligent function module the instruction works for. The setting range of each CPU module is shown below.
  - FX5UJ CPU module: 1H to 8H (K1 to K8)
  - FX5U/FX5UC CPU module: 1H to 10H (K1 to K16)

|            |            | Module No. 1                |                             | Module No. 2                |            | Module No. 3                | Module No. 4          | Module No. 5                |
|------------|------------|-----------------------------|-----------------------------|-----------------------------|------------|-----------------------------|-----------------------|-----------------------------|
| CPU module | I/O module | Intelligent function module | Extension power supply unit | Intelligent function module | I/O module | Intelligent function module | Bus conversion module | Intelligent function module |

- A module number is automatically assigned to each intelligent function module connected to a CPU module. The module number is assigned in the way "No. 1 → No. 2 → No. 3 ..." starting from the equipment nearest the CPU module.
- 16-bit RAM memories are built in an intelligent function module, and they are called buffer memories. The contents of buffer memories vary depending on the purpose of control of each intelligent function module, and the setting range is from K0 to K4294967295.
- The number of read data is specified by (n), and the setting range is from K1 to K65535.

- If this instruction is executed in an interrupt program with the priority 1, operation error (3580H) occurs. This instruction operates in an interrupt program with the priority 2 or 3.
- If this instruction is executed to an FX3 intelligent function module within an interrupt program, operation error (3580H) occurs.

# Writing 1-word/2-word data to another module (32-bit specification)

## TOD(P), DTOD(P)

FX5S

FX5UJ

FX5U

FX5UC

### • TOD(P)

These instructions write the (n) points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

### • DTOD(P)

These instructions write the (n) × 2 points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

\*1 Only the DTOD(P) instruction can be used.

## Processing details

### ■TOD(P)

- These instructions write the (n) points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

- When a constant is specified in (s2), (n) words of the same data (the value specified by (s2)) is written starting from the specified buffer memory address.

## ■DTOD(P)

- These instructions write the  $(n) \times 2$  points of data in the device starting from the one specified by (s2) to the buffer memory address specified by (s1) in intelligent function module specified by (U/H).

- When a constant is specified in (s2),  $(n) \times 2$  words of the same data (the value specified by (s2)) is written starting from the specified buffer memory address.

## Precautions

- For the nibble of a bit device specified by (s2), specify K1 to K4 in the TOD(P) instruction and K1 to K8 in the DTOD(P) instruction.

## Operation error

## 8.28 Logging Instructions

### Setting trigger logging

#### LOGTRG

**FX5S****FX5UJ****FX5U****FX5UC**

This instruction generates a trigger condition for the specified logging setting number in trigger logging.

| Ladder diagram                                                                    | Structured text    |
|-----------------------------------------------------------------------------------|--------------------|
|  | ENO:=LOGTRG(EN,s); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

#### Setting data

##### ■Descriptions, ranges, and data types

| Operand | Description            | Range  | Data type            | Data type (label) |
|---------|------------------------|--------|----------------------|-------------------|
| (s)     | Logging setting number | 1 to 4 | 16-bit signed binary | ANY16             |
| EN      | Execution condition    | —      | Bit                  | BOOL              |
| ENO     | Execution result       | —      | Bit                  | BOOL              |

##### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○                         | —     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

#### Processing details

- This instruction generates a trigger for trigger logging with the logging setting number specified by (s).
- Specify a value 1 to 4 in (s).
- The LOGTRG instruction turns on the special relay (logging trigger) with the logging setting number in the device specified by (s) and executes trigger logging for the specified number of records.
- The instruction is enabled when "When trigger instruction executed" is selected in the "Trigger condition".
- Even if the LOGTRG instruction is executed, no processing is performed in the following cases.
  - A logging setting number in which an item other than "When trigger instruction executed" is selected in the "Trigger condition" is specified.
  - A logging setting number with no setting is specified.
  - A logging setting number specifying the execution of continuous logging is specified.
  - Another LOGTRG instruction is executed without executing the LOGTRGR instruction after a LOGTRG instruction was executed once.

#### Operation error

| Error code (SD0/SD8067) | Description                                                              |
|-------------------------|--------------------------------------------------------------------------|
| 3405H                   | The value set in (s) is other than the following.<br>$1 \leq (s) \leq 4$ |

# Resetting trigger logging

## LOGTRGR

**FX5S****FX5UJ****FX5U****FX5UC**

This instruction resets the trigger condition of the specified logging setting number.

| Ladder diagram                                                                    | Structured text     |
|-----------------------------------------------------------------------------------|---------------------|
|  | ENO:=LOGTRGR(EN,s); |
| FBD/LD                                                                            |                     |
|  |                     |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description            | Range  | Data type            | Data type (label) |
|---------|------------------------|--------|----------------------|-------------------|
| (s)     | Logging setting number | 1 to 4 | 16-bit signed binary | ANY16             |
| EN      | Execution condition    | —      | Bit                  | BOOL              |
| ENO     | Execution result       | —      | Bit                  | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○                         | —     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- This instruction resets the LOGTRG instruction of the logging setting number specified by (s). The instruction disables the LOGTRG instruction of the specified trigger logging setting number.
- The LOGTRGR instruction turns off the special relay (logging completion, logging trigger, and after logging trigger) with the logging setting number in the device specified by (s).

## Precautions

When the LOGTRGR instruction is executed after the LOGTRG instruction is executed in the same scan, the LOGTRG instruction becomes invalid.

## Operation error

| Error code (SD0/8067) | Description                                                              |
|-----------------------|--------------------------------------------------------------------------|
| 3405H                 | The value set in (s) is other than the following.<br>$1 \leq (s) \leq 4$ |

# 8.29 Real-time Monitor Function Instruction

## RTM

FX5S    FX5UJ    FX5U    FX5UC

The real-time monitor function monitors the data when the instruction is executed.

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=RTM(EN);   |

### FBD/LD

### Processing details

Depending on the monitor condition of the real-time monitor function, the data collection timing is when the instruction is executed. When the command input turns on as shown below, the data can be monitored at any timing.

### Related devices

| Device | Name                                         | Description                                                           |
|--------|----------------------------------------------|-----------------------------------------------------------------------|
| SD1484 | Real-time monitor internal buffer free space | The amount of free space of the internal buffer is stored in K bytes. |

### Precautions

- More than one RTM instruction must not be issued during one scan. The data missing occurs.
- In the following case, even if the RTM instruction is executed, the procession is not performed.
  - When the collection timing of the real time monitor is not set to "RTM Instruction Specification" by GX LogViewer.
  - When the RTM instruction is executed in the interrupt program.

### Operation error

There is no operation error.

<sup>\*1</sup> Only S can be used.

## Processing details

- In programs using step ladder instructions, a step relay S is assigned to each process based on machine operations, and sequences of input condition and output control are programmed as circuits connected to contacts (STL contacts) of state relays.
- In a step ladder program, a step relay S is regarded as one control process, and a sequence of input conditions and output controls are programmed in a state relay. Because the preceding process is stopped when the program execution proceeds to the next process, a machine can be controlled using simple sequences for each process.
- The step relay number specified by STL instruction is assigned to the State. The start and completion of the State use SET instruction, OUT instruction, RST instruction, and ZRST instruction.
- Program a step ladder program starting from the initial state relay in the order of state relay ON status transfer. Make sure to put the RETSTL instruction at the end of a step ladder program. The RETSTL instruction is omissible anywhere other than the last Step Ladder.

The actual step ladder program is as follows.

- A step ladder program is expressed as a relay ladder, but it can be created according to the machine control flow using state relays. A state relay consists of a drive coil and contact (STL contact) in the same way as other relays. Use SET or OUT instructions to drive a coil, and use STL instructions for a contact.
- The table below shows operations of internal circuits connected to the state relays,

#### Internal circuit diagram operation

|                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Execution in the contact ON status                            | When a state relay turns ON, a connected circuit (internal circuit) is activated with a STL contact.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Execution in the contact OFF status (for one operation cycle) | When a condition (transfer condition) provided between state relays is satisfied, the next state relay turns ON, and the state relay which was been ON before hand turns OFF (transfer operation). In the state relay ON status transfer process, both state relays are ON for one operation cycle.<br>In the next operation cycle after the ON status is transferred to the next state relay, the former state relay is reset to OFF. A drive instruction connected to the bus line of the reset state relay is executed in the contact OFF status for one operation cycle regardless of the actual contact status before the drive instruction.<br>When the transfer state relay is used in a contact instruction, however, the contact image is executed in the OFF status immediately after the transfer condition is satisfied. |
| Non-execution                                                 | An instruction is not executed in the contact OFF status after the operation cycle where the instruction was executed in the contact OFF status (jump status).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- The figure below shows the timing chart of the state relay (internal circuit) activation status.

- Each state relay has three functions, driving a load, specifying a transfer destination and specifying a transfer condition. Such as the following program, driving a load and then transition processing. In a state relay without any load, the drive processing is not required.

## ■Operation of program

The step ladder program operates as follows.

\*1 It is always necessary to program to drive an output.

\*2 Output coils can be used again in different state relays.

\*3 Each OUT and SET instruction for step relays automatically resets the transfer source, and has the self-holding function.

\*4 One step relay number can only be used once.

\*5 It is not possible to place a pointer immediately after the STL instruction. If a pointer is placed, a program error (33E2H) occurs.

### Point

When the step relay is latched, the ON/OFF status is backed up by nonvolatile memory against power failure. Use this type of state relay if the operation should be restarted from the last point before power failure. These relays hold the operation status also at the time of RUN to STOP. If it RUN(s) again, the operation will be resumed from the State before STOP.

## ■Related devices

| Device           | Name                  | Description                                                                                                                                    |
|------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| SM8040           | STL transfer disable  | When SM8040 is set to ON, transfer of the ON status is disabled among all state relays.                                                        |
| SM8046           | STL state ON          | When the step relay turns on, SM8046 turns on automatically.                                                                                   |
| SM8047           | Enable STL monitoring | When SM8047 is turned on, it stores in SD8040 to SD8047 sequentially from the young number of the step relay which operates in the step relay. |
| SD8040 to SD8047 | ON step relay numbers | The turned-on step relay number is stored in SD8040 to SD8047 (Max. 8 points) sequentially from the smaller number.                            |

## Precautions

- When the step relay is not latched, step relay clears at power supply ON→OFF or RUN→STOP. If the State is valid and power supply ON→OFF or PLC RUN→STOP, operation can not be restarted from the last point before power-supply ON→OFF or RUN→STOP.
- The STL/RETSTL instruction cannot be used in a project including an SFC program.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------|
| 33E3H                   | The STL instruction or RETSTL instruction is programmed between FOR-NEXT.                                              |
| 33E5H                   | The STL instruction or RETSTL instruction is programmed in an interrupt program, subroutine program or function block. |
|                         | The frequency of use of the STL instruction is not consistent with that of the RETSTL instruction.                     |
| 33F3H                   | Three or more STL instructions with the same step relay No. are programmed.                                            |

# 10 PID CONTROL INSTRUCTION

| (d)     | —                           | ○ <sup>*1</sup>           | ○     | — | —           | —  | —                      | —        | — | —  | —      |

<sup>\*1</sup> Only D, SD, R can be used.

### Processing details

When the target value (s1), measured value (s2), and parameters (s3) to (s3)+6 are set and a program is executed, the operation result (MV) is stored to the output value (d) at every sampling time (s3). For details, refer to the  MELSEC iQ-F FX5 User's Manual (Application).

## Precautions

- When auto tuning is not used, twenty-five devices are occupied from the head device specified in (s3).
- When auto tuning (limit cycle method) is used, twenty-nine devices are occupied from the head device specified in (s3).
- When auto tuning (step response method) is used, the number of devices occupied from the devices specified in (s3) differs depending on the ON/OFF status of b8 of (s3)+1.

| Operation of b8 | Occupied device points                                               |
|-----------------|----------------------------------------------------------------------|
| ON              | Twenty-eight devices are occupied from the device specified in (s3). |
| OFF             | Twenty-five devices are occupied from the device specified in (s3).  |

- Two or more PID instructions can be executed at the same time. (There is no limitation in the number of loops.) However, make sure that (s3), (d) and other operands specified in each instruction are different to each other.
- For the output value (MV) in the PID instruction, specify an unlatched data register. If specifying a latched data register, make sure to clear the backup contents when the PLC mode is set to RUN using the following program.

(1): Latched data register number specified to (d)

## Operation error

# 11 SFC PROGRAM INSTRUCTIONS

## Point

This chapter describes the instructions used in SFC programs. For details on SFC programs, refer to the following.

📖 MELSEC iQ-F FX5 Programming Manual (Program Design)

## 11.1 SFC Control Instructions

### Checking the status of a step

LD, LDI, AND, ANI, OR, ORI [S□/BL□\S□]

FX5S

FX5UJ

FX5U

FX5UC

- LD: Normally open contact, LDI: Normally closed contact

These instructions output the status (active or inactive) of the specified step as the operation result.

- AND: Normally open contact series connection, ANI: Normally closed contact series connection

These instructions perform an AND operation between the status (active or inactive) of the specified step and the previous operation result(s), and output the operation result.

- OR: Single normally open contact parallel connection, ORI: Single normally closed contact parallel connection

These instructions perform an OR operation between the status (active or inactive) of the specified step and the previous operation result(s), and output the operation result.

| Ladder diagram                                                                      | Structured text |
|-------------------------------------------------------------------------------------|-----------------|
|  | Not supported.  |

#### FBD/LD

Not supported.

### Setting data

#### ■ Descriptions, ranges, and data types

| Operand | Description              | Range | Data type | Data type (label) |
|---------|--------------------------|-------|-----------|-------------------|
| (s)     | Device used as a contact | —     | Bit       | ANY_BOOL          |

## ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (BL□\S□) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-----------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |                 |
| (s)     | ○*1*2                       | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○*2             |

\*1 Only S can be used.

\*2 Indexing is not available.

## Processing details

- These instructions check whether the specified step in the specified block is active or not.
- The status (on or off) of each contact will be as follows depending on the status (active or inactive) of the specified step.

| Status of the specified step | Contact of the normally open contact instruction | Contact of the normally closed contact instruction |
|------------------------------|--------------------------------------------------|----------------------------------------------------|
| Active                       | ON                                               | OFF                                                |
| Inactive*1                   | OFF                                              | ON                                                 |

\*1 Including the cases where no corresponding step exists in an SFC program.

- The following table summarizes specification methods of steps.

| Program          |                                    | Specification method                                                                                                                                |
|------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| SFC program      | Specifying a step in current block | Use S□.                                                                                                                                             |
|                  | Specifying a step in another block | Use BL□\S□.                                                                                                                                         |
| Sequence program |                                    | <ul style="list-style-type: none"> <li>• Use BL□\S□.</li> <li>• If the block No. is not specified, the target block will be the block 0.</li> </ul> |

- If the block No. or the step No. specified is out of range, both of the normally open contact and normally closed contact turn off.
- If the instruction is executed while no SFC program exists (SM320 (Presence/absence of SFC program) is off) or SM321 (Start/stop SFC program) is off and both of the specified block No. and step No. are within the range, the normally open contact instruction turns off and the normally closed contact instruction turns on.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------|
| 2820H                   | When a block No. is specified, the specified block No. is out of the range of 0 to 31.                          |
|                         | When a block No. is specified, the specified step No. is out of the range of 0 to 511.                          |
|                         | When a block No. is specified, the step relay No. assigned the specified step is out of the range of 0 to 4095. |
|                         | When a block No. is not specified, the specified step No. is out of the range of 0 to 4095.                     |
| 3582H                   | The SFC control instruction is used in the interrupt routine program.                                           |

## Checking the status of a block

### LD, LDI, AND, ANI, OR, ORI [BL□]

FX5S

FX5UJ

FX5U

FX5UC

- LD: Normally open contact, LDI: Normally closed contact

These instructions output the status (active or inactive) of the specified block as the operation result.

- AND: Normally open contact series connection, ANI: Normally closed contact series connection

These instructions perform an AND operation between the status (active or inactive) of the specified block and the previous operation result(s), and output the operation result.

- OR: Single normally open contact parallel connection, ORI: Single normally closed contact parallel connection

These instructions perform an OR operation between the status (active or inactive) of the specified block and the previous operation result(s), and output the operation result.

| Ladder diagram                                                                     | Structured text |
|------------------------------------------------------------------------------------|-----------------|
|  | Not supported.  |

#### FBD/LD

Not supported.

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description              | Range | Data type | Data type (label) |
|---------|--------------------------|-------|-----------|-------------------|
| (s)     | Device used as a contact | —     | Bit       | ANY_BOOL          |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (BL□) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |              |
| (s)     | —                           | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○            |

## Processing details

- These instructions check whether the specified block is active or not.
- The status (on or off) of each contact will be as follows depending on the status (active or inactive) of the specified block.

| Status of the specified block | Contact of the normally open contact instruction | Contact of the normally closed contact instruction |
|-------------------------------|--------------------------------------------------|----------------------------------------------------|
| Active                        | ON                                               | OFF                                                |
| Inactive <sup>*1</sup>        | OFF                                              | ON                                                 |

\*1 Including the cases where no corresponding block exists in an SFC program.

- If the block No. specified is out of range, both of the normally open contact and normally closed contact turn off.
- If the instruction is executed while no SFC program exists (SM320 (Presence/absence of SFC program) is off) or SM321 (Start/stop SFC program) is off and the specified block No. is within the range, the normally open contact instruction turns off and the normally closed contact instruction turns on.

## Operation error

| Error code (SD0/SD8067) | Description                                                           |
|-------------------------|-----------------------------------------------------------------------|
| 2820H                   | When the specified block No. is out of the range of 0 to 31.          |
| 3582H                   | The SFC control instruction is used in the interrupt routine program. |

## Batch-reading the status of steps

### MOV(P) [KnS□/BL□\KnS□]

FX5S

FX5UJ

FX5U

FX5UC

These instructions batch-read (in units of 16-bit binary data) the status (active or inactive) of steps in the specified block, and store the read data in the specified device. (Kn: K1 to K4)

| Ladder diagram                                                                    | Structured text                           |
|-----------------------------------------------------------------------------------|-------------------------------------------|
|  | ENO:=MOV(EN,s,d);<br>ENO:=MOV(P)(EN,s,d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                            | Range | Data type            | Data type (label) |
|---------|--------------------------------------------------------|-------|----------------------|-------------------|
| (s)     | Device number where the transfer source data is stored | —     | 16-bit signed binary | ANY16             |
| (d)     | Transfer destination device number                     | —     | 16-bit signed binary | ANY16             |
| EN      | Execution condition                                    | —     | Bit                  | BOOL              |
| ENO     | Execution result                                       | —     | Bit                  | BOOL              |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (BL□\S□) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-----------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |                 |
| (s)     | ○*1                         | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○               |
| (d)     | ○*2                         | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —               |

\*1 Only S can be used.

\*2 Other than S can be used.

## Processing details

- These instructions batch-read (in units of 16-bit binary data) the status (active or inactive) of steps in the specified block. K1 to K4 can be specified to the nibble specification of the step relay (S).
- When a block is not specified, the status (active or inactive) of the following block is read.
  - Sequence program: Block 0
  - SFC program (within the action): Block where the instruction is executed (current block)
- The read data are stored in the device specified by (d). When the step is active, 1 is stored. When the step is inactive, 0 is stored.

[Example: when K4 is specified to the nibble specification]

[Example: when K3 is specified to the nibble specification]

- When there is a missing step No., 0 is stored in the corresponding bit.

**Ex.**

When the step No.5 and No.8 are missing in the specified block (The status of each step is stored in other bits.)

- If no block is specified, when the read target range exceeds the maximum step No. in the block, undefined values will be stored.

**Ex.**

When the last step No. in the specified block is S26 and the status of steps (S16 to S31) are read to D1. (The status of each step is stored in other bits.)

- If the read target range exceeds the number of steps in the specified block, 0 is stored in the bits exceeding the existing step No.

**Ex.**

When the last step No. in the specified block is S26 and the status of steps (S16 to S31) are read to D1. (The status of each step is stored in other bits.)

- If the block 0 does not exist, when the instruction is executed in the sequence program, undefined values are stored in all bits.
- In the case of "with block specification," if a non-existent block is specified, the bit data to be read will be 0.
- If a non-existent step is at the beginning of the data to be read, the bit data to be read will be 0.
- If readout is performed in the absence of the SFC program, the following operation will be performed depending on the presence/absence of the SFC program setting and block setting in the CPU parameters.

| SFC program setting | Block specification | Instruction operation                                          |
|---------------------|---------------------|----------------------------------------------------------------|
| Not use             | None                | The device value of the step relay will be transferred to (d). |
|                     | Present             | The bit data to be read becomes "0".                           |
| Use                 | None                | The bit data to be read becomes "0".                           |
|                     | Present             | The bit data to be read becomes "0".                           |

## Operation error

| Error code (SD0/SD8067) | Description                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------|
| 2820H                   | When a block No. is specified, the specified block No. is out of the range of 0 to 31.         |
|                         | When a block No. is specified, the specified step No. is out of the range of 0 to 511.         |
|                         | When the step relay No. where the specified step is assigned is out of the range of 0 to 4095. |
|                         | When a block No. is not specified, the specified step No. is out of the range of 0 to 4095.    |
| 2821H                   | When a step relay (s) is specified to (d).                                                     |
| 3582H                   | The SFC control instruction is used in the interrupt routine program.                          |

### Point

Use a digit specification to specify a step. (Kn: K1 to K4)

- To specify a step in the current block of an SFC program, use Kn□.
- To specify a step in another block of an SFC program, use BL□\KnS□.
- To specify a step of a sequence program, use BL□\KnS□.

## DMOV(P) [KnS□/BL□\KnS□]

FX5S

FX5UJ

FX5U

FX5UC

These instructions batch-read (in units of 32-bit binary data) the status (active or inactive) of steps in the specified block, and store the read data in the specified device. (Kn: K1 to K8)

\*1 Only S can be used.

\*2 Other than S can be used.

## Processing details

- These instructions batch-read (in units of 32-bit binary data) the status (active or inactive) of steps in the specified block. K1 to K8 can be specified to the nibble specification of the step relay (S).
- When a block is not specified, the status (active or inactive) of the following block is read.
  - Sequence program: Block 0
  - SFC program (within the action): Block where the instruction is executed (current block)
- The read data are stored in the device specified by (d). When the step is active, 1 is stored. When the step is inactive, 0 is stored.

[Example: when K8 is specified to the nibble specification]

[Example: when K3 is specified to the nibble specification]

- When there is a missing step No., 0 is stored in the corresponding bit.

**Ex.**

When the step No.5, 8, 18, and 29 are missing in the specified block. (The status of each step is stored in other bits.)

- If no block is specified, when the read target range exceeds the maximum step No. in the block, undefined values will be stored.

**Ex.**

When the last step No. in the specified block is S26 and the status of steps (S0 to S31) are read to D0 and D1. (The status of each step is stored in other bits.)

- If the read target range exceeds the number of steps in the specified block, 0 is stored in the bits exceeding the existing step No.

**Ex.**

When the last step No. in the specified block is S26 and the status of steps (S0 to S31) are read to D0 and D1. (The status of each step is stored in other bits.)

- If block 0 does not exist, when the instruction is executed in the sequence program, undefined values are stored in all bits.
- In the case of "with block specification," if a non-existent block is specified, the bit data to be read will be 0.
- If a non-existent step is at the beginning of the data to be read, the bit data to be read will be 0.
- If readout is performed in the absence of the SFC program, the following operation will be performed depending on the presence/absence of the SFC program setting and block setting in the CPU parameters.

| SFC program setting | Block specification | Instruction operation                                          |
|---------------------|---------------------|----------------------------------------------------------------|
| Not use             | None                | The device value of the step relay will be transferred to (d). |
|                     | Present             | The bit data to be read becomes "0".                           |
| Use                 | None                | The bit data to be read becomes "0".                           |
|                     | Present             | The bit data to be read becomes "0".                           |

## Operation error

| Error code (SD0/SD8067) | Description                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------|
| 2820H                   | When a block No. is specified, the specified block No. is out of the range of 0 to 31.         |
|                         | When a block No. is specified, the specified step No. is out of the range of 0 to 511.         |
|                         | When the step relay No. where the specified step is assigned is out of the range of 0 to 4095. |
|                         | When a block No. is not specified, the specified step No. is out of the range of 0 to 4095.    |
| 2821H                   | When a step relay (s) is specified to (d).                                                     |
| 3582H                   | The SFC control instruction is used in the interrupt routine program.                          |

\*1 Only S can be used.

\*2 Other than S can be used.

## Processing details

- These instructions batch-read (in units of the specified number of words starting from the specified step) the status (active or inactive) of steps in the specified block. K1 to K4 can be specified to the nibble specification of the step relay (S).
- When a block is not specified, the status (active or inactive) of the following block is read.
- Sequence program: Block 0
- SFC program (within the action): Block where the instruction is executed (current block)
- The read data are stored in the device specified by (d).

[Example: when K4 is specified to the nibble specification]

[Example: when K3 (the numbers of transfers: 03) is specified to the nibble specification]

(1) 0 is stored.

- When there is a missing step No., 0 is stored in the corresponding bit.

#### Ex.

When the step No.5 and No.8 are missing in the specified block (The status of each step is stored in other bits.)

- In the case of "without block specification," if the read target range is as shown below, undefined data will be stored.
  - When the maximum step No. in the block is exceeded
  - If block 0 does not exist, when the instruction is executed in the sequence program

#### Ex.

When the last step No. in the block is 26 and the status of the steps (two words from S0) is read to D0 and D1. (The status of each step is stored in other bits.)

- In the case of "with block specification," if the read target range is as shown below, undefined data will be stored.
  - When the maximum step No. in the block is exceeded
  - When a non-existent step is at the beginning of the read target range
- If a block is specified and block 0 does not exist, when the instruction that does not specify a block is executed in the sequence program, 0 is stored.

#### Ex.

When the last step No. in the block is 26 and the status of the steps (two words from S0) is read to D0 and D1. (The status of each step is stored in other bits.)

- If a block is specified, when the block that does not exist is specified, 0 is read and stored in all bits.
- If no block is specified, when the read target range exceeds the maximum step No. (S4095), the data from the first step No. to the maximum step No. will be read.
- When the read target range exceeds the maximum device No. (such as D7999), the data from the first device No. to the maximum device No. are transferred.
- When the first device is out of the range of the device No., an error occurs and data is not read.
- If readout is performed in the absence of the SFC program, the following operation will be performed depending on the presence/absence of the SFC program setting and block setting in the CPU parameters.

| SFC program setting | Block specification | Instruction operation                                          |
|---------------------|---------------------|----------------------------------------------------------------|
| Not use             | None                | The device value of the step relay will be transferred to (d). |
|                     | Present             | The bit data to be read becomes "0".                           |
| Use                 | None                | The bit data to be read becomes "0".                           |
|                     | Present             | The bit data to be read becomes "0".                           |

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                    |

| ENO     | Execution result                                    | —     | Bit       | BOOL              |

### Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (BL□) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |              |
| (d)     | —                           | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○            |

### Processing details

- This instruction temporarily stops the step sequence in the specified block.
- All the steps become inactive immediately after execution of the instruction.
- The coil output status caused by the OUT instruction at the temporary stop depends on the status of SM325 (output mode at pausing a block).

| Status of SM325 | Coil output status by using the OUT instruction                             |
|-----------------|-----------------------------------------------------------------------------|
| On              | During the stop, the coil output remains the state immediately before stop. |
| Off             | The coil output turns off at stop.                                          |

### Precautions

If the sequence is stopped while SM325 is off, coil HOLD steps become inactive. The sequence cannot be restarted with the hold status. If the sequence is stopped while SM325 is on, the sequence can be restarted with the hold status.

## Operation error

| Error code (SD0) | Description                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------|
| 31A1H            | The specified block does not exist.                                                                                    |
|                  | The instruction is executed when no SFC program (scan execution type) exists or SM321 (start/stop SFC program) is off. |
| 31A2H            | The specified block No. is out of the range.                                                                           |
| 3582H            | The SFC control instruction is used in the interrupt routine program.                                                  |

### Point

Operation of the PAUSE and RESTART instructions depends on the combination of the SM325 status and step hold status. For details, refer to the following.

 MELSEC iQ-F FX5 Programming Manual (Program Design)

# Restarting a block

## RSTART [BL□]

FX5S

FX5UJ

FX5U

FX5UC

This instruction releases the temporary stop, and restarts the sequence from the step where the sequence was stopped in the specified block.

| Ladder diagram                                                                    | Structured text     |
|-----------------------------------------------------------------------------------|---------------------|
|  | ENO:=RSTART(EN, d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Execution condition

| Instruction | Execution condition                                                               |
|-------------|-----------------------------------------------------------------------------------|
| RSTART      |  |

### Setting data

### Descriptions, ranges, and data types

| Operand | Description                                    | Range | Data type | Data type (label) |
|---------|------------------------------------------------|-------|-----------|-------------------|
| (d)     | Block No. where the temporary stop is released | —     | Bit       | ANY_BOOL          |
| EN      | Execution condition                            | —     | Bit       | BOOL              |
| ENO     | Execution result                               | —     | Bit       | BOOL              |

### Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (BL□) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |              |
| (d)     | —                           | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○            |

### Processing details

- This instruction restarts the sequence from the step where the sequence was stopped in the specified block. Operation HOLD steps (with or without transition check), which have been stopped with operation hold status, restart operation with the hold status.
- After the step sequence is restarted, the operation of the PLS instruction and the instructions which are executed only on the rising edge depends on the status of SM325 (output mode at pausing a block).

| Status of SM325           | Operation of the PLS instruction and the instructions executed on the rising edge |
|---------------------------|-----------------------------------------------------------------------------------|
| On (Coil output is held.) | The instruction is not executed.                                                  |
| Off (Coil output is off.) | The instruction is executed again.                                                |

### Precautions

If the sequence is stopped while SM325 is off, coil HOLD steps become inactive. The sequence cannot be restarted with the hold status. If the sequence is stopped while SM325 is on, the sequence can be restarted with the hold status.

## Operation error

| Error code (SD0) | Description                                                                                                            |

|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |                    |
| (d)     | ○*1*2                       | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○*2                |

\*1 Only S can be used.  
\*2 Indexing is not available.

## Processing details

- This instruction activates the specified step in the specified block. The operation of the specified block will be as follows depending on the status (active or inactive) of the specified block.

| Status of the specified block | Operation                                                                                                            |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------|
| Inactive                      | The specified block is activated at execution of the instruction, and starts the processing from the specified step. |
| Active                        | The specified step is newly activated while the step which has already been active continues processing.             |

- If the instruction is executed to an active step, the instruction is ignored and processing will continue. Note that if the specified step is holding the operating status, the hold status is reset. The step becomes a normal step, and executes the action and transition.
- If no block is specified, the following block is targeted depending on the execution program type.
  - Sequence program: Block 0
  - SFC program (within the action): Block where the instruction is executed (current block)

## Precautions

- In a simultaneous sequence, specify and activate all the steps by using the SET instruction (Activating a step). If there is any inactive step left, a convergence is not performed. Likewise, if the RST instruction (Deactivating a step) is executed to a single step in a simultaneous sequence, a convergence condition is not satisfied.
- The own step cannot be specified as the step No. within the action of the SFC program. If specified, an error occurs.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------|
| 31A1H                   | The specified block does not exist.                                                              |
|                         | The control target block does not exist. (SET/RST/OUT S□)                                        |
| 31A2H                   | When a block No. is specified, the specified block No. is out of the range of 0 to 31.           |
| 31B1H                   | The instruction is executed when no SFC program (Start/stop SFC program) exists or SM321 is off. |
|                         | No specified step exists in the specified block. (SET/RST/OUT BL□\S□/S□)                         |
| 31B2H                   | The specified step No. is out of the range (0 to 511).                                           |
| 31B5H                   | The current step is specified within the action.                                                 |
| 3582H                   | The SFC control instruction is used in the interrupt routine program.                            |

# Deactivating a step

## RST [S□/BL□\S□]

- FX5S
- FX5UJ
- FX5U
- FX5UC

This instruction deactivates the specified step.

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                                | Range | Data type | Data type (label) |
|---------|----------------------------------------------------------------------------|-------|-----------|-------------------|
| (d)     | Step No. to be deactivated<br>(Target bit device number to be reset (off)) | —     | Bit       | ANY_BOOL          |
| EN      | Execution condition                                                        | —     | Bit       | BOOL              |
| ENO     | Execution result                                                           | —     | Bit       | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (BL□\S□) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-----------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |                 |
| (d)     | ○*1*2                       | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○*2             |

- \*1 Only S can be used.
- \*2 Indexing is not available.

## Processing details

- This instruction deactivates the specified step in the specified block.
- When the number of active steps in the specified becomes 0, the specified block will be inactive.
- If the instruction is executed to an inactive step, the instruction is ignored and processing will continue.
- If no block is specified, the following block will be deactivated.
  - Sequence program: Block 0
  - SFC program (within the action): Block where the instruction is executed (current block)

## Precautions

- If the step termination instruction is executed for a step in a parallel branch, the parallel convergence condition will not be met.
- The own step cannot be specified as the step No. within the action of the SFC program. If the own step No. is specified as the specified step No., an error will occur.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------|

\*1 Only S can be used.

\*2 Indexing is not available.

## Processing details

- When the drive contact is on, this instruction activates the specified step in the specified block. Same as the operation by the SET instruction (SET S□/BL□\S□). (  Page 976 Activating a step)
- When the drive contact is off, this instruction deactivates the specified step in the specified block. That is the same operation executed by the RST instruction (RST S□/BL□\S□). (  Page 978 Deactivating a step) (However, when the instruction is executed within the action, the instruction is ignored. That is the different operation executed by the RST instruction.)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                      |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                              | Range | Data type | Data type (label) |
|---------|------------------------------------------|-------|-----------|-------------------|
| (d1)    | A first step No. to be batch-deactivated | —     | Bit       | ANY_BOOL          |
| (d2)    | A last step No. to be batch-deactivated  | —     | Bit       | ANY_BOOL          |
| EN      | Execution condition                      | —     | Bit       | BOOL              |
| ENO     | Execution result                         | —     | Bit       | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (BL□\S□) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-----------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |                 |
| (d1)    | ○*1                         | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○               |
| (d2)    | ○*1                         | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○               |

\*1 Only S can be used.

## Processing details

- This instruction batch-deactivates the activated steps within the range specified by (d1) and (d2). When the instruction is executed and the number of activated steps in the corresponding block becomes 0, the block will be deactivated.
- Unify the device specified to (d1) or (d2) into S□ or BL□\S□. When devices are not unified (Example: [ZRST S2 BL0\S5]), an operation error occurs and the status of the step is not changed.
- If no block is specified, make sure to specify the step Nos. so as to be (d1) < (d2). When (d1) ≥ (d2), only one step No. that is specified to (d1) will be deactivated. When a step that does not exist is specified to (d1) or (d2), the steps that exist in the specified range will be deactivated.

- When a block is specified, specification is possible over blocks. Make sure to specify the block Nos. so as to be (d1) < (d2).  
When (d1) ≥ (d2), only one step No. that is specified to (d1) will be deactivated. When a block that does not exist is specified to (d1) or (d2), the steps that exist in the specified range will be deactivated.

**Ex.**

When executing [ZRST BL1\S20 BL5\S10] to SFC programs having the following configuration.

- Block 1, 3, 5: No block exists.
- Block 2: S0 to S5 exist.
- Block 4: S0 to S3 are exist.

| Block No.     | Step No.              | Deactivating target  |
|---------------|-----------------------|----------------------|
| 1 (No target) | 21 to 511 (No target) | Excluded from target |
| 2             | 0 to 5                | Deactivates          |
|               | 6 to 511 (No target)  | Excluded from target |
| 3 (No target) | 0 to 511 (No target)  | Excluded from target |
| 4             | 0 to 3                | Deactivates          |
|               | 4 to 511 (No target)  | Excluded from target |
| 5 (No target) | 0 to 10 (No target)   | Excluded from target |

- If the current step is specified so as to be in the deactivating target range within the action, the step will not be deactivated.
- If no block is specified, the following specified block step will be deactivated. Specification over blocks is not possible.
  - When the instruction is executed in a sequence program: Block 0
  - When the instruction is executed in an SFC program (within the action): Block where the instruction is executed (current block)

**Ex.**

When executing [ZRST S0 S511] in an within the action of block1 to SFC programs having the following configuration.

- Block 1: S0 to S255 exist.
- Block 2: S0 to S255 exist.

| Block No. | Step No.                | Deactivating target  |
|-----------|-------------------------|----------------------|
| 1         | 0 to 255                | Deactivates          |
|           | 256 to 511 (Not target) | Excluded from target |
| 2         | 0 to 255                | Excluded from target |
|           | 256 to 511 (No target)  | Excluded from target |

- When one of the following conditions are satisfied, the instruction will be ignored.
  - No steps in the specified range exist.
  - If a block is specified, when no SFC program exists.
  - If an SFC program exists, the instruction is executed when SM321 (Start/stop SFC program) is off.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------|
| 2820H                      | When a block No. is specified, the specified block No. of (d1) or (d2) is out of the range of 0 to 31.      |
|                            | When a block No. is specified, the specified step No. of (d1) or (d2) is out of the range of 0 to 511.      |
|                            | When a block No. is not specified, the specified step No. of (d1) or (d2) is out of the range of 0 to 4095. |
| 3405H                      | When S□ and BL□\S□ are mixed in the specified devices to (d1) and (d2).                                     |
| 3582H                      | The SFC control instruction is used in the interrupt routine program.                                       |

# 12 NETWORK COMMON INSTRUCTION

## Target networks and target station types

Each link dedicated instruction allows access to a station on a network other than the own station network.

The following table lists the target stations of each instruction.

| Instruction symbol    | Target station (another station)                                                                                                                                                                                   |                                                                                                                                                                                          |

<sup>\*1</sup> These instructions can access the following personal computer interface boards having the SEND/RECV functions.  
CC-Link IE Field Network interface board, CC-Link IE Controller Network interface board, MELSECNET/H interface board, and MELSECNET/10 interface board

## Specifications of character string data specified by link dedicated instructions

Some operands specified in link dedicated instructions are specified in character strings. The following table summarizes the specifications of character string data specified.

| Instruction symbol | Applicable operand | Specifications of character string data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

# 12.1 Link Dedicated Instructions

## Reading data from another station programmable controller

### GP.READ

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction reads data from a device in another station programmable controller. (In units of words)  
CC-Link IE TSN is compatible only with FX5U/FX5UC CPU module.

\*1 If completion status ((s1)+1) is "Channel in use (dedicated instruction) (error codes: D25AH to D25BH)", data is not stored.

Point

- The continuous area (a maximum of 960 words) specified by the read data length ((s1)+9) is required in the read data storage device (d1).
- The number of resends (s1)+7 must be set every time the instruction is executed.

Processing details

- The instruction reads data by the specified number of words ((s1)+9) from the target station head device (s2) into the own station head device (after (d1)). Specify the target stations in control data ((s1)+4) and ((s1)+5). Upon completion of reading the device data specified by (s2), the completion device specified by (d2) turns on.
- For the target stations that can be specified, refer to the following.

Page 986 Target networks and target station types

- When executing multiple link dedicated instructions concurrently, be careful not to overlap the channels of the link dedicated instructions. Multiple link dedicated instructions specifying the same channel cannot be used concurrently.

- The execution of the GP.READ instruction and whether it has been completed normally or completed with an error can be checked with the completion device (d2) or completion status indication device (d2)+1.

| Device                                     | Operation                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d2)                     | The device turns on during the END processing for the scan in which the GP.READ instruction is completed, and turns off during the next END processing.                                                                                                                                                                                                                 |
| Completion status indication device (d2)+1 | <p>The device turns on or off depending on the completion status of the GP.READ instruction.</p> <p>When completed normally: The device does not change (remains off).</p> <p>When completed with an error: The device turns on during the END processing for the scan in which the GP.READ instruction is completed, and turns off during the next END processing.</p> |

- The following figure shows the execution timing of the GP.READ instruction.

When completed normally

When completed with an error

- Read processing is performed only once on the rising edge when the read command turns on.

## Operation error

# Reading data from another station programmable controller (with notification)

## GP.SREAD

FX5S

FX5UJ

FX5U

FX5UC

This instruction reads data from a device in another station programmable controller. (In units of words)

After the data reading is completed by the GP.SREAD instruction, the device of the other station is turned on. The other station can recognize that data has been read by the GP.SREAD instruction.

CC-Link IE TSN is compatible only with FX5U/FX5UC CPU module.

\*1 In the case of the ST language and the FBD/LD language, U displays as Un.

\*2 For the specifications of the string data to be specified, refer to the following.

( Page 987 Specifications of character string data specified by link dedicated instructions)

\*3 The continuous area specified by the read data length (s1)+9 is required.

\*4 Digit specified bit type label cannot be used.

\*1 If completion status ((s1)+1) is "Channel in use (dedicated instruction) (error codes: D25AH to D25BH)", data is not stored.

### Point

- The continuous area (a maximum of 960 words) specified by the read data length ((s1)+9) is required in the read data storage device (d1).
- The number of resends (s1)+7 must be set every time the instruction is executed.

## Processing details

- The instruction reads data by the specified number of words ((s1)+9) from the target station head device (s2) into the own station word device (after (d1)). Specify the target stations in control data ((s1)+4) and ((s1)+5). Upon completion of reading the device data specified by (s2), the completion device specified by (d2) turns on. In target station, upon completion of sending the device data specified by (s2), the device specified by (d3) turns on.
- For the target stations that can be specified, refer to the following.

☞ Page 986 Target networks and target station types

- When executing multiple link dedicated instructions concurrently, be careful not to overlap the channels of the link dedicated instructions. Multiple link dedicated instructions specifying the same channel cannot be used concurrently.

- The execution of the GP.SREAD instruction and whether it has been completed normally or completed with an error can be checked with the completion device (d2) or completion status indication device (d2)+1.

| Device                                     | Operation                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d2)                     | The device turns on during the END processing for the scan in which the GP.SREAD instruction is completed, and turns off during the next END processing.                                                                                                                                                                                                   |
| Completion status indication device (d2)+1 | The device turns on or off depending on the completion status of the GP.SREAD instruction.<br>When completed normally: The device does not change (remains off).<br>When completed with an error: The device turns on during the END processing for the scan in which the GP.SREAD instruction is completed, and turns off during the next END processing. |

- The following figure shows the execution timing of the GP.SREAD instruction.

When completed normally

When completed with an error

- Read processing is performed only once on the rising edge when the read command turns on.

## Operation error

# Writing data to another station programmable controller

## GP.WRITE

**FX5S****FX5UJ****FX5U****FX5UC**

This instruction writes data to the device in another station programmable controller. (In units of words)

CC-Link IE TSN is compatible only with FX5U/FX5UC CPU module.

| Ladder diagram | Structured text                   |
|----------------|-----------------------------------|
|                | ENO:=GP_WRITE(EN,Un,s1,s2,d1,d2); |

## FBD/LD

("GP\_WRITE" enters □.)

## Setting data

\*<sup>1</sup> If completion status ((s1)+1) is "Channel in use (dedicated instruction) (error codes: D25AH to D25BH)", data is not stored.

- The continuous area (a maximum of 960 words) specified by the write data length ((s1)+9) is required in the write data storage device (d1).
- When a number from 1 to 120 is specified for the target station number, the GP.WRITE instruction should be executed with the execution type set to "Arrival acknowledgment used" to improve data reliability. When a number from 81H to A0H or FFH is specified for the target station number, the GP.WRITE instruction should be executed with the execution type set to "No arrival acknowledgment".
- When performing device writing to the same station from multiple stations, do not overlap the write timing. When the execution type is set to "No arrival acknowledgment", successful completion results in the write source station if communication is completed successfully even when the sending data contains an error. Also, even when the sending data is normal, a timeout results in the write source station if the GP.WRITE instruction is executed for the same station from multiple stations.
- The number of resends (s1)+7 must be set every time the instruction is executed.

## Processing details

- The instruction writes data by the specified number of words ((s1)+9) from the own station head device (s2) into the target station word devices. Specify the target stations in control data ((s1)+4) and ((s1)+5). Upon completion of writing device data to target station, the completion device specified by (d2) turns on.
- For the target stations that can be specified, refer to the following.

☞ Page 986 Target networks and target station types

- When executing multiple link dedicated instructions concurrently, be careful not to overlap the channels of the link dedicated instructions. Multiple link dedicated instructions specifying the same channel cannot be used concurrently.
- The execution of the GP.WRITE instruction and whether it has been completed normally or completed with an error can be checked with the completion device (d2) or completion status indication device (d2)+1.

| Device                                     | Operation                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d2)                     | The device turns on during the END processing for the scan in which the GP.WRITE instruction is completed, and turns off during the next END processing.                                                                                                                                                                                                   |
| Completion status indication device (d2)+1 | The device turns on or off depending on the completion status of the GP.WRITE instruction.<br>When completed normally: The device does not change (remains off).<br>When completed with an error: The device turns on during the END processing for the scan in which the GP.WRITE instruction is completed, and turns off during the next END processing. |

- The following figure shows the execution timing of the GP.WRITE instruction.

When completed normally

When completed with an error

- Write processing is performed only once on the rising edge when the write command turns on.

## Operation error

# Writing data to another station programmable controller (with notification)

## GP.SWRITE

FX5S

FX5UJ

FX5U

FX5UC

This instruction writes data to the device in another station programmable controller. (In units of words)

After the data writing is completed by the GP.SWRITE instruction, the device of the other station is turned on. The other station can recognize that data has been written by the GP.SWRITE instruction.

CC-Link IE TSN is compatible only with FX5U/FX5UC CPU module.

\*1 If completion status ((s1)+1) is "Channel in use (dedicated instruction) (error codes: D25AH to D25BH)", data is not stored.

- The continuous area (a maximum of 960 words) specified by the write data length ((s1)+9) is required in the write data storage device (d1).
- When a number from 1 to 120 is specified for the target station number, the GP.SWRITE instruction should be executed with the execution type set to "Arrival acknowledgment used" to improve data reliability. When a number from 81H to A0H or FFH is specified for the target station number, the GP.SWRITE instruction should be executed with the execution type set to "No arrival acknowledgment".
- When performing device writing to the same station from multiple stations, do not overlap the write timing. When the execution type is set to "No arrival acknowledgment", successful completion results in the write source station if communication is completed successfully even when the sending data contains an error. Also, even when the sending data is normal, a timeout results in the write source station if the GP.SWRITE instruction is executed for the same station from multiple stations.
- The number of resends (s1)+7 must be set every time the instruction is executed.

## Processing details

- The instruction writes data by the specified number of words ((s1)+9) from the own station head device (s2) into the target station word devices. Specify the target stations in control data ((s1)+4) and ((s1)+5). Upon completion of writing device data to target station, the completion device specified by (d2) turns on. In the other station, upon completion of writing the device data specified by (s2), the device specified by (d3) turns on.
- For the target stations that can be specified, refer to the following.

Page 986 Target networks and target station types

- When executing multiple link dedicated instructions concurrently, be careful not to overlap the channels of the link dedicated instructions. Multiple link dedicated instructions specifying the same channel cannot be used concurrently.
- The execution of the GP.SWRITE instruction and whether it has been completed normally or completed with an error can be checked with the completion device (d2) or completion status indication device (d2)+1.

| Device                                     | Operation                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d2)                     | The device turns on during the END processing for the scan in which the GP.SWRITE instruction is completed, and turns off during the next END processing.                                                                                                                                                                                                    |
| Completion status indication device (d2)+1 | The device turns on or off depending on the completion status of the GP.SWRITE instruction.<br>When completed normally: The device does not change (remains off).<br>When completed with an error: The device turns on during the END processing for the scan in which the GP.SWRITE instruction is completed, and turns off during the next END processing. |

- The following figure shows the execution timing of the GP.SWRITE instruction.

When completed normally

When completed with an error

- Write processing is performed only once on the rising edge when the write command turns on.

# Sending data to another station programmable controller

## GP.SEND

**FX5S****FX5UJ****FX5U****FX5UC**

This instruction sends data to another station programmable controller.

CC-Link IE TSN is compatible only with FX5U/FX5UC CPU module.

<sup>\*1</sup> If completion status ((s1)+1) is "Channel in use (dedicated instruction) (error codes: D25AH to D25BH)", data is not stored.

- The continuous area (a maximum of 960 words) specified by the send data length ((s1)+9) is required in the send data storage device (s2).
- When a number from 1 to 120 is specified for the target station number, the instruction should be executed with the execution type set to "Arrival acknowledgment used" to improve data reliability. When a group number or all stations are specified, the instruction should be executed with the execution type set to "No arrival acknowledgment".
- When sending data to the same channel in the receiving station, execute the instruction after data has been read by the GP.RECV instruction in the receiving station. When the execution type is set to "No arrival acknowledgment", successful completion results in the sending station if communication is completed successfully even when the sending data contains an error. Also, even when the sending data is normal, a timeout results in the sending station if the instructions are executed for the same station from multiple stations.
- With the execution type set to "Arrival acknowledgment used", if the sending station sends data to the same channel in the receiving station before the receiving station reads data using the GP.RECV instruction, a buffer full error results in the sending station.

- When multiple network modules are mounted in the target station, specify the network number and station number of the network module that receives a request from the own station.

(Example: In the following figure, specify station No. 1 of network No. 1. (Station No. 5 of network No. 2. cannot be specified.))

No.: Network No.

St.: Station No.

- The number of resends (s1)+7 must be set every time the instruction is executed.

## Processing details

- The instruction sends data by the specified number of words ((s1)+9) from the own station head device (s2) into the specified channel of a target station. The data that has been sent is stored in the channel specified by (s2) in the target station. To read the sent data in the target station, use the GP.RECV instruction. Upon completion of sending data to the target station number, the completion device specified by (d) turns on.
- For the target stations that can be specified, refer to the following.

Page 986 Target networks and target station types

- When executing multiple link dedicated instructions concurrently, be careful not to overlap the channels of the link dedicated instructions. Multiple link dedicated instructions specifying the same channel cannot be used concurrently.
- The execution of the GP.SEND instruction and whether it has been completed normally or completed with an error can be checked with the completion device (d) or completion status indication device (d)+1.

| Device                                    | Operation                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d)                     | The device turns on during the END processing for the scan in which the GP.SEND instruction is completed, and turns off during the next END processing.                                                                                                                                                                                                  |
| Completion status indication device (d)+1 | The device turns on or off depending on the completion status of the GP.SEND instruction.<br>When completed normally: The device does not change (remains off).<br>When completed with an error: The device turns on during the END processing for the scan in which the GP.SEND instruction is completed, and turns off during the next END processing. |

- The following figure shows the execution timing of the SEND instruction.

When completed normally

When completed with an error

- Send processing is performed only once on the rising edge when the send command turns on.

## Operation error

# Receiving data from another station programmable controller

## GP.RECV

FX5S

FX5UJ

FX5U

FX5UC

This instruction reads data received from another station programmable controller. (For the main routine program)

CC-Link IE TSN is compatible only with FX5U/FX5UC CPU module.

<sup>\*1</sup> If completion status ((s1)+1) is "Channel in use (dedicated instruction) (error codes: D25AH to D25BH)", data is not stored.

- The continuous area (a maximum of 960 words) specified by the receive data length ((s1)+9) is required in the receive data storage device (d1).
- The GP.RECV instruction is executed every time the bit of the corresponding channel in the GP.RECV instruction execution request area (SB0030 to SB0037) in the buffer memory turns on (with receive data).
- If multiple network modules having the same network number are installed in the receiving station, specify "U" for the network module that will receive data according to the GP.RECV instruction.

(Example: To execute the GP.RECV instruction in the station number 3 in response to the GP.SEND instruction from the station number 1, specify "U2".)

## Processing details

- This instruction reads data, which were sent from another station by the SEND instruction, from the specified channel of the own station module to the own station word device (after (d1)). When the data reading from the specified channel of the own station is completed, the completion device (d2) turns on.
- For the target stations that can be specified, refer to the following.

📖 Page 986 Target networks and target station types

- The data received from the sending station is stored in the own station channel specified by the sending station and the corresponding bit in the GP.RECV instruction execution request area corresponding to each channel is set to on. When the corresponding bit in the GP.RECV instruction execution request area is set to on, the received data is read from the receive data storage channel. The following table lists the GP.RECV instruction execution request areas.

| Name of GP.RECV instruction execution request area     | Device number/address of corresponding bit |
|--------------------------------------------------------|--------------------------------------------|
| GP.RECV execution request flag Channel 1               | SB0030                                     |
| GP.RECV execution request flag Channel 2               | SB0031                                     |
| GP.RECV execution request flag Channel 3 <sup>*1</sup> | SB0032                                     |
| GP.RECV execution request flag Channel 4 <sup>*1</sup> | SB0033                                     |
| GP.RECV execution request flag Channel 5 <sup>*1</sup> | SB0034                                     |
| GP.RECV execution request flag Channel 6 <sup>*1</sup> | SB0035                                     |
| GP.RECV execution request flag Channel 7 <sup>*1</sup> | SB0036                                     |
| GP.RECV execution request flag Channel 8 <sup>*1</sup> | SB0037                                     |

<sup>\*1</sup> Compatible only with FX5-CCLGN-MS.

- When executing multiple link dedicated instructions concurrently, be careful not to overlap the channels of the link dedicated instructions. Multiple link dedicated instructions specifying the same channel cannot be used concurrently.
- The execution of the GP.RECV instruction and whether it has been completed normally or completed with an error can be checked with the completion device (d2) or completion status indication device (d2)+1.

| Device                                     | Operation                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d2)                     | The device turns on during the END processing for the scan in which the GP.RECV instruction is completed, and turns off during the next END processing.                                                                                                                                                                                                  |
| Completion status indication device (d2)+1 | The device turns on or off depending on the completion status of the GP.RECV instruction.<br>When completed normally: The device does not change (remains off).<br>When completed with an error: The device turns on during the END processing for the scan in which the GP.RECV instruction is completed, and turns off during the next END processing. |

• The following figure shows the execution timing of the GP.RECV instruction.

When completed normally

For the execution timing, refer to the following instruction.

( Page 1016 GP.SEND)

When completed with an error

• Read processing is performed only once on the rising edge when the read command turns on.

## Operation error

| Error code ((s)+1) | Description                                                                                                                                                                                                                                                                                                                   |

# 13 Ethernet INSTRUCTION

## 13.1 Built-in Ethernet Function Instruction

### Opening a connection

#### SP.SOCOPEN

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction opens a connection.

\*1 User: Data to be set before the execution of the instruction. System: The CPU module stores the execution result of the instruction.

\*2 When Unpassive open is selected, the target device IP address and target device port number are ignored.

\*3 Of the host station port numbers, 1 to 1023 (0001H to 03FFH) are generally reserved port numbers and 61440 to 65534 (F000H to FFFE<sup>H</sup>) are used by other communication functions. Thus, using 1024 to 5548 and 5570 to 61439 (0400H to 15ACH and 15C2H to EFFFH) as the port numbers is recommended. Do not specify 5549 to 5569 (15ADH to 15C1H) since they are used by the system.

## Processing details

This instruction opens the connection specified by (s1).

The setting value used by the open processing is selected by (s2)+0.

The completion of the SP.SOCOPEN instruction can be checked using the completion devices (d)+0 and (d)+1.

- Completion device (d)+0: Turns ON during the END processing for the scan in which the SP.SOCOPEN instruction is completed, and turns OFF during the next END processing.
- Completion device (d)+1: Turns ON or OFF depending on the status of when the SP.SOCOPEN instruction is completed.

| Status                       | Description                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                  |
| When completed with an error | The device turns ON during the END processing for the scan in which the SP.SOCOPEN instruction is completed, and turns OFF during the next END processing. |

The connection in which no protocol is set with the parameter can be opened and used. In this case, specify 8000H in (s2)+0 and the contents of the open processing in (s2)+2 to (s2)+6.

For details, refer to [MELSEC iQ-F FX5 User's Manual \(Communication\)](#).

## Operation error

\*1 System: The CPU module stores the execution result of the instruction.

## Processing details

This instruction closes the connection specified by (s1). (Connection disconnection)

The completion of the SP.SOCCLOSE instruction can be checked using the completion devices (d)+0 and (d)+1.

- Completion device (d)+0: Turns ON during the END processing for the scan in which the SP.SOCCLOSE instruction is completed, and turns OFF during the next END processing.
- Completion device (d)+1: Turns ON or OFF depending on the status when the SP.SOCCLOSE instruction is completed.

| Status                       | Description                                                                                                                                                 |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                   |
| When completed with an error | The device turns ON during the END processing for the scan in which the SP.SOCCLOSE instruction is completed, and turns OFF during the next END processing. |

For details, refer to MELSEC iQ-F FX5 User's Manual (Communication).

## Operation error

| Error code (SD0/SD8067) | Description                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------|
| 3405H                   | The connection number specified by (s1) is other than 1 to 8.                                   |
| 2820H                   | The device number specified by (s2) or (d) is outside the range of the number of device points. |
| 2822H                   | Device that cannot be specified is specified.                                                   |
| 3582H                   | When an instruction which cannot be used in interruption routine program is used.               |

### Point

Do not execute the SP.SOCCLOSE instruction when Passive open is selected. Since the open completion signal and open request signal of the corresponding connection turn OFF and close processing is executed, the communication is disabled.

| (s2)+1           | Completion status   | The status at the completion of the instruction is stored.<br>0000H: Completed successfully<br>Other than 0000H: Completed with an error (error code)<br>For error codes, refer to MELSEC iQ-F FX5 User's Manual (Communication). | —             | System               |
| (d1)+0           | Receive data length | The data length of the data read from the socket communication receive data area is stored. (Number of bytes)                                                                                                                     | 0 to 2046     | System               |
| (d1)+1 to (d1)+n | Receive data        | The data read from the socket communication receive data area is sequentially stored.                                                                                                                                             | —             | System               |

\*1 System: The CPU module stores the execution result of the instruction.

### Point

- When the SP.SOCRCV instruction is executed, reading data from the socket communication receive data area is executed with the END processing. Thus, executing the SP.SOCRCV instruction extends the scan time.
- When the data of odd-number of bytes is received, invalid data is stored in the higher byte of the device where the last receive data is stored.

## Processing details

In the END processing after the execution of the SP.SOCRCV instruction, the receive data of the connection specified by (s1) is read from the socket communication receive data area.

The completion of the SP.SOCRCV instruction can be checked using the completion devices (d2)+0 and (d2)+1.

- Completion device (d2)+0: Turns ON during the END processing for the scan in which the SP.SOCRCV instruction is completed, and turns OFF during the next END processing.
- Completion device (d2)+1: Turns ON or OFF depending on the status when the SP.SOCRCV instruction is completed.

| Status                       | Description                                                                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                 |
| When completed with an error | The device turns ON during the END processing for the scan in which the SP.SOCRCV instruction is completed, and turns OFF during the next END processing. |

The following figure shows the timing of the receive processing with the SP.SOCRCV instruction.

For details, refer to MELSEC iQ-F FX5 User's Manual (Communication).

| (s3)+1 to (s3)+n | Send data         | Specifies the send data.                                                                                                                                                                                                          | —             | User                 |

<sup>\*1</sup> User: Data to be set before the execution of the instruction. System: The CPU module stores the execution result of the instruction.

### Point

When TCP is used, specify send data length that is smaller than the maximum window size of the target device (Receive data buffer of TCP). Data whose size exceeds the maximum window size of the target device cannot be sent.

13

## Processing details

This instruction send the data set by (s3) to the target device of the connection specified by (s1).

The completion of the SP.SOCSEND instruction can be checked using the completion devices (d)+0 and (d)+1.

- Completion device (d)+0: Turns ON during the END processing for the scan in which the SP.SOCSEND instruction is completed, and turns OFF during the next END processing.
- Completion device (d)+1: Turns ON or OFF depending on the status when the SP.SOCSEND instruction is completed.

| Status                       | Description                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                  |
| When completed with an error | The device turns ON during the END processing for the scan in which the SP.SOCSEND instruction is completed, and turns OFF during the next END processing. |

The following figure shows the timing of the send processing with the SP.SOCSND instruction.

<Sending control method>

For details, refer to [MELSEC iQ-F FX5 User's Manual \(Communication\)](#).

## Operation error

| (d)+4          | Application setting area  | <div style="text-align: center;">           b15b14b13 to b10 b9 b8 b7 to b0<br/>           (d)+4 <span style="border: 1px solid black; padding: 2px;">3</span> 0 <span style="border: 1px solid black; padding: 2px;">2</span> <span style="border: 1px solid black; padding: 2px;">1</span> 0         </div> <p>[1] Communication method (protocol)<br/>0: TCP/IP<br/>1: UDP/IP</p> <p>[2] Procedure of the socket communication function<br/>1: Non-protocol method</p> <p>[3] Open method<br/>00: Active open or UDP/IP<br/>10: Unpassive open<br/>11: Fullpassive open</p> | As shown on the left <sup>*2</sup>                                          |                      |

\*1 System: The CPU module stores the execution result of the instruction.

\*2 When the instruction is executed for a connection that is not open, 0H is returned.

\*3 Of the host station port numbers, 1 to 1023 (0001H to 03FFH) are generally reserved port numbers and 61440 to 65534 (F000H to FFFE) are used by other communication functions. Thus, using 1024 to 5548 and 5570 to 61439 (0400H to 15ACH and 15C2H to EFFFH) as the port numbers is recommended. Do not specify 5549 to 5569 (15ADH to 15C1H) since they are used by the system.

## Processing details

This instruction reads the connection information of the connection specified by (s1).

For details, refer to MELSEC iQ-F FX5 User's Manual (Communication).

## Operation error

| (s2)+1 | Completion status | The status at the completion of the instruction is stored.<br>0000H: Completed successfully<br>Other than 0000H: Completed with an error (error code)<br>For error codes, refer to MELSEC iQ-F FX5 User's Manual (Communication). | —             | System               |

\*1 System: The CPU module stores the execution result of the instruction.

## Processing details

These instructions read the data for the number of words specified by (n) from the socket communication receive data area of the connection specified by (s1) to the devices from the device specified by (d) onwards. No processing is performed when (n) is 0.

### Point

- When (n) is 1, the receive data length can be read. By doing this, the device for storing the receive data can be changed when the SP.SOCRCV instruction is executed.

For details, refer to MELSEC iQ-F FX5 User's Manual (Communication).

## Precautions

- Even when the S(P).SOCRDATA instructions are executed, the socket communication receive data area is not cleared and the receiving status signal does not change. Therefore, the next receive data is not stored in the socket communication receive data area.
- To update receive data, use the SP.SOCRCV instruction to read the receive data.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------|
| 3405H                      | The connection number specified by (s1) is other than 1 to 8.                                         |
| 2820H                      | The device number specified by (s2), (d), or (n) is outside the range of the number of device points. |
| 2822H                      | Device that cannot be specified is specified.                                                         |

# 13.3 Predefined Protocol Support Function Instruction

## Executing the registered protocols

### SP.ECPRTCL

FX5S

FX5UJ

FX5U

FX5UC

This instruction executes the communication protocol registered using the engineering tool.

| Ladder diagram                                                                    | Structured text                    |

| (s3)+3  | Execution protocol number 2                | Specify the number of the protocol to be executed second.                                                                                                                                                                                                                                                                                                                        | 0, 1 to 64    |                      |
| (s3)+4  | Execution protocol number 3                | Specify the number of the protocol to be executed third.                                                                                                                                                                                                                                                                                                                         | 0, 1 to 64    |                      |
| (s3)+5  | Execution protocol number 4                | Specify the number of the protocol to be executed fourth.                                                                                                                                                                                                                                                                                                                        | 0, 1 to 64    |                      |
| (s3)+6  | Execution protocol number 5                | Specify the number of the protocol to be executed fifth.                                                                                                                                                                                                                                                                                                                         | 0, 1 to 64    |                      |
| (s3)+7  | Execution protocol number 6                | Specify the number of the protocol to be executed sixth.                                                                                                                                                                                                                                                                                                                         | 0, 1 to 64    |                      |
| (s3)+8  | Execution protocol number 7                | Specify the number of the protocol to be executed seventh.                                                                                                                                                                                                                                                                                                                       | 0, 1 to 64    |                      |
| (s3)+9  | Execution protocol number 8                | Specify the number of the protocol to be executed eighth.                                                                                                                                                                                                                                                                                                                        | 0, 1 to 64    |                      |
| (s3)+10 | Collation match<br>Receive packet number 1 | If receiving is included in the communication type of the protocol that has been executed first, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the first protocol, "0" is stored.                                                                        | 0, 1 to 16    | System               |
| (s3)+11 | Collation match<br>Receive packet number 2 | If receiving is included in the communication type of the protocol that has been executed second, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the second protocol, "0" is stored. If the number of protocols executed is less than 2, "0" is stored.   | 0, 1 to 16    |                      |
| (s3)+12 | Collation match<br>Receive packet number 3 | If receiving is included in the communication type of the protocol that has been executed third, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the third protocol, "0" is stored. If the number of protocols executed is less than 3, "0" is stored.     | 0, 1 to 16    |                      |
| (s3)+13 | Collation match<br>Receive packet number 4 | If receiving is included in the communication type of the protocol that has been executed fourth, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the fourth protocol, "0" is stored. If the number of protocols executed is less than 4, "0" is stored.   | 0, 1 to 16    |                      |
| (s3)+14 | Collation match<br>Receive packet number 5 | If receiving is included in the communication type of the protocol that has been executed fifth, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the fifth protocol, "0" is stored. If the number of protocols executed is less than 5, "0" is stored.     | 0, 1 to 16    |                      |
| (s3)+15 | Collation match<br>Receive packet number 6 | If receiving is included in the communication type of the protocol that has been executed sixth, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the sixth protocol, "0" is stored. If the number of protocols executed is less than 6, "0" is stored.     | 0, 1 to 16    |                      |
| (s3)+16 | Collation match<br>Receive packet number 7 | If receiving is included in the communication type of the protocol that has been executed seventh, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the seventh protocol, "0" is stored. If the number of protocols executed is less than 7, "0" is stored. | 0, 1 to 16    |                      |
| (s3)+17 | Collation match<br>Receive packet number 8 | If receiving is included in the communication type of the protocol that has been executed eighth, the receive packet number successful in collation match is stored. If the communication type is "receive only", "0" is stored. If an error occurs during execution of the eighth protocol, "0" is stored. If the number of protocols executed is less than 8, "0" is stored.   | 0, 1 to 16    |                      |

\*1 User: Data to be set before the execution of the instruction. System: The CPU module stores the execution result of the instruction.

## Processing details

This instruction executes the protocol registered using the engineering tool. Using the connection specified by (s1), the instruction executes the protocol in accordance with the control data stored in the device specified by (s3) and later. The instruction continuously executes as many protocols as specified by (s2) (a maximum of 8 protocols) at one time.

The number of executed protocols is stored in the device specified by (s3)+0.

The completion of the SP.ECPRTCL instruction can be checked using the completion devices (d)+0 and (d)+1.

- Completion device (d)+0: Turns ON during the END processing for the scan in which the SP.ECPRTCL instruction is completed, and turns OFF during the next END processing.
- Completion device (d)+1: Turns ON or OFF depending on the status when the SP.ECPRTCL instruction is completed.

| Status                       | Description                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                  |
| When completed with an error | The device turns ON during the END processing for the scan in which the SP.ECPRTCL instruction is completed, and turns OFF during the next END processing. |

For details, refer to [MELSEC iQ-F FX5 User's Manual \(Communication\)](#).

## Precautions

- If an error occurs in the mth protocol while multiple protocols are being executed, the instruction does not execute the "m+1"th protocol and after and is completed with an error.
- The connections for which the SP.ECPRTCL instruction can be executed are only those for which "Communication protocol" is specified for the communication means.
- If a cancel request is received during execution of the mth protocol while multiple protocols are executed continuously, the following is stored in (s3).

| Device   | Item                                      | Description                                                                                |
|----------|-------------------------------------------|--------------------------------------------------------------------------------------------|
| (s3)+0   | Resulting number of executed protocols    | The executed protocol number.                                                              |
| (s3)+1   | Completion status                         | The error codes.                                                                           |
| (s3)+10  | Collation match Receive packet number 1   | The receive packet number successful in collation match for the already executed protocol. |
| ⋮        | ⋮                                         |                                                                                            |
| (s3)+m+8 | Collation match Receive packet number m-1 |                                                                                            |

- If same instructions are executed for the same connection, the subsequent instruction is ignored and is not executed until the preceding instruction is completed.
- The SP.ECPRTCL instruction itself does not open/close a connection and therefore the SP.SOCOPEN/SP.SOCCLOSE instructions need to be used to open/close the connection.

Page 1030 SP.SOCOPEN Refer to the Page 1033 SP.SOCCLOSE

## Operation error

| Error code<br>(SD0/SD8067) | Description                                    |
|----------------------------|------------------------------------------------|
| 2820H                      | The device used exceeded the specified range.  |
| 2821H                      | The device used to store data are overlapping. |
| 2822H                      | Device that cannot be specified is specified.  |
| 3405H                      | The input data was out of range.               |

# 13.4 SLMP Frame Send Instruction

## Sending the SLMP frame

### SP.SLMPSND

FX5S

FX5UJ

FX5U

FX5UC

This instruction sends SLMP messages to an SLMP-compatible device.

| Ladder diagram                                                                    | Structured text                     |
|-----------------------------------------------------------------------------------|-------------------------------------|
|  | ENO:=SP_SLMPSND(EN,Un,s1,s2,d1,d2); |

\*1 If (s1)+0 is set to "0: Without arrival check", receive data is not set. Set 0 in (s1)+0 in the following cases:

- When a command that does not return a response message is used
- When a response message is not referred to

\*2 When "0" or "255" is specified to the fourth octet of the IP address of the target device, a send error occurs and the SP.SLMPSND instruction is completed with an error.

In addition, the error code (C1CDH (SP.SLMPSND instruction message send error)) is stored in the completion status.

- When data of the error completion type (the 7th bit of (s1)+0) is set to "1" and "0", the operations are shown below.

| Error completion type<br>(The 7th bit of (s1)+0)   | Completion status<br>(s1)+1 | Clock setting flag<br>(s1)+12 | Clock data<br>(s1)+13 to 16                      | IP address of error<br>detected device<br>(s1)+17, 18 |
|----------------------------------------------------|-----------------------------|-------------------------------|--------------------------------------------------|-------------------------------------------------------|
| 0: Do not set the data at completion with an error | Normal completion           | 0: Invalid                    | 0 (Clear)                                        | 0 (Clear)                                             |

| (s2)+1           | Monitoring timer    | This timer sets the waiting time for the target device that received a request message to wait for response to processing request issued to the request destination. (Unit: Increments of 250 ms)<br>• 0: Infinite wait<br>• 1 to 65535: 1 to 65535 × 250 ms | 0 to 65535    | User   |
| (s2)+2 to (s2)+n | Request data        | The request data of the SLMP message is stored.                                                                                                                                                                                                              | —             | User   |

## Response frame

| Device           | Item                 | Description                                                                                                                                  | Setting range | Set by |
|------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| (d1)+0           | Response data length | The data length from the end code to the response data is stored. (In units of bytes)                                                        | 2 to 2000     | System |
| (d1)+1           | End code             | The result of command processing is stored. In normal end, 0 is stored. In abnormal end, an error code set by the target device is stored.*1 | —             | System |
| (d1)+2 to (d1)+n | Response data        | Execution results for the request data are set. (Some commands do not return response data.)                                                 | —*2           | System |

\*1 For the set error code and the corresponding error description, check the specifications of the target device.

\*2 For details of the response data, refer to the MELSEC iQ-F FX5 User's Manual (Communication).

## Processing details

- This instruction sends the request frame in the device specified by (s2) and later to the target device specified by the target device IP address in the control data. When a response message is received from the target device, it is stored in the device specified by (d1).

The following figures show the request data and the response data in normal/abnormal end.

### ●Request data

### ●Response data

(When completed)

(When failed)

- The SP.SLMPSND instruction communicates using UDP. Set the target device to use UDP.
- The SP.SLMPSND instruction communicates in binary code. Match the setting of the target device also with the binary code.
- The normal or abnormal completion of the SP.SLMPSND instruction can be confirmed with the completion device (d2) specified in the setting data and the completion status indication device (d2)+1.

| Device                                     | Operation                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d2)                     | The device is turned on by END processing for the scan in which the SP.SLMPSND instruction is completed and turned off by next END processing.                                                                                                                                                                                        |
| Completion status indication device (d2)+1 | The device is turned on or off depending on the status when the SP.SLMPSND instruction is completed.<br>When completed normally: The device remains off.<br>When completed abnormally: The device is turned on by END processing for the scan in which the SP.SLMPSND instruction is completed and turned off by next END processing. |

**Ex.**

Sending "Device Read (command: 0401H)" which reads the value in D100 to D102

●Request data

## Precautions

Specify the arrival monitoring time ((s1)+11) of the control data and monitoring timer ((s2)+1) of the request frame so that the arrival monitoring time  $\geq$  monitoring timer.

- (1) Request message
- (2) Processing request from target device to request destination
- (3) Processing response from request destination to target device
- (4) Response message

## Point

The SP.SLMPSND instruction is successfully completed even if the target device returns an abnormal response. When the SP.SLMPSND instruction is completed successfully, whether the response is normal or abnormal can be identified by the end code of the response frame. When an abnormal response is returned, check the manual of the SLMP-compatible device being used and take corrective action.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                        |
|----------------------------|------------------------------------------------------------------------------------|
| 3405H                      | The value set to (s1)+2 as own station channel is out of the range, 1 to 9.        |
|                            | The value set to (s2)+0 as the request data length is out of the range, 1 to 2000. |

Upon completion with an error, the completion status indication device (d2)+1 is turned on and an error code is stored in the completion status (s1)+1. For the error code stored in the completion status (s1)+1, refer to the following.

# 13.5 File Transfer Function Instruction

## Sending FTP client files

### SP.FTPPUT

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction sends files in the CPU module, which are specified by (s2), to the folder path of the FTP server, which is specified by (s3).

| Ladder                                                                            | ST                                |

## Processing details

- This instruction sends files in the CPU module, which are specified by (s2), to the folder path of the FTP server, which is specified by (s3). The CPU module opens a connection with the FTP server set in the module parameters (FTP Client Settings) at execution of the instruction, and closes a connection after sending files. For details on the parameter setting, refer to the following.

📖 MELSEC iQ-F FX5 User's Manual (Communication)

- The total number of files to be transferred by the SP.FTPPUT instruction is stored in (s1)+2, and the number of transferred files is stored in (s1)+3.

- Specify the transfer source drive number (2) of the CPU module, the folder path where the files are stored, and the file name (including an extension) in (s2) in Unicode string. The only files which can be specified as a path are those stored under the LOGGING or DEBUG folder in the SD memory card (Drive 2). The maximum number of characters used in a file path is 255. The maximum number of characters used in a path, excluding the file name, is 246 (not including a delimiter). Use one-byte '\' or '/' as a delimiter to specify the boundaries between the elements in a file path.

- (1) Drive numbers that can be specified are 2. (MELSEC iQ-F FX5 User's Manual (Application))  
 (2) Use one-byte ':' or '/' as a delimiter of the drive number.  
 (3) Use one-byte '\' or '/' as a delimiter of the folder path and file.  
 (4) The specified file name should include an extension.

- Wild card characters (\*, ?) can be used in the file name or the extension specified in (s2).

| Symbol | Description                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------|
| *      | An asterisk '*' is replaced with any character or string (including none) in a file name.                           |
| ?      | A question mark '?' is replaced with a character (excluding none) in a file name. ('?' can be used multiple times.) |

Wild card characters do not recognize periods.

Using wild card characters in the following ways results in an error.

- Two or more asterisks '\*\*' are used in a file name (before the period) or an extension. (Example: \*abc\*.txt)
- An asterisk '\*' and a question mark '?' are used in a file name (before the period) or an extension. (Example: \*ab?.txt)

When any wild card character is used, the number of files that can be transferred is determined by the total size of the file names of the specified files. The specified files can be transferred when the number of these files and the total size of the file names satisfy the following condition. If a file transfer function instruction is executed without satisfying the following condition, the instruction completes with an error.

$$(F_i + N \cdot M) + 1 < 32768 \text{ [bytes]}$$

N: Total number of files that match the wild card specification

F<sub>i</sub>: Total size of the file names that match the wild card specification

M: Specific information size (Fixed value: 6 bytes)

- If an error occurs in any one of the files to be transferred during execution of the SP.FTPPUT instruction, the transfer processing will be stopped upon detection of the error, and the rest of target files will not be transferred.
- If the number of characters in the file path which includes a file name and an extension exceeds 255, files will not be transferred even though the wild card specification conditions are satisfied.

- Specify the folder path of the transfer destination FTP server in (s3) in Unicode string. The specified folder path shall be a relative path from home directory of the FTP server. Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path.\*1 The maximum number of characters used in the folder path is 255. Note that the total number of characters in a folder path (including the delimiter at the end) and the file name specified in (s2) must be within the maximum path length supported by the transfer destination FTP server. The delimiter at the end of a string can be omitted. When omitted, '\' is assumed to be set at the end. If a nonexistent folder path is specified, a folder is automatically created by the system at execution of the instruction, and then the processing is performed.

- (1) Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path.\*1  
 (2) The delimiter at the end of string can be omitted.

\*1 Note that '\' cannot be used as a delimiter for some FTP servers.

- If a NULL character is specified by (s3) or only "0000H" is specified for the device, the CPU module directly accesses under the home directory of the FTP server. For details, follow the FTP server specifications.
- If a file with the same name exists in the transfer destination, the file will be overwritten.
- If a large file to be transferred is specified in the FTP client function, it may take long to transfer the file. For example: When the scan time is 5 ms, the time required for the SP.FTPPUT instruction to transfer a 16 MB file is approx. 548 seconds.
- The normal or abnormal completion of the SP.FTPPUT instruction can be confirmed with the completion device (d) specified in the setting data and the completion status indication device (d)+1.

| Device                                    | Operation                                                                                                                                                                                                                                                                                                                           |

| Completion device (d)                     | The device is turned on by END processing for the scan in which the SP.FTPPUT instruction is completed and turned off by next END processing.                                                                                                                                                                                       |
| Completion status indication device (d)+1 | The device is turned on or off depending on the status when the SP.FTPPUT instruction is completed.<br>When completed normally: The device remains off.<br>When completed abnormally: The device is turned on by END processing for the scan in which the SP.FTPPUT instruction is completed and turned off by next END processing. |

- The following figure shows the execution timing of the SP.FTPPUT instruction.

- (1) SM1392 turns on during the END processing after the CPU module is connected to the FTP server.  
 (2) Values are stored upon completion of the instruction.  
 (3) When all files have been transferred, SM1392 turns off.

- SM1392 (FTP client connection status) is on while the CPU module is connected to the FTP server, and SM1392 turns off when disconnected.
- SM753 (File access in progress) turns on while the SP.FTPPUT instruction is being executed. While SM753 is on, the SP.FTPPUT instruction cannot be executed. If executed, no processing is performed.
- If the SP.FTPPUT instruction is executed while the SP.FTPPUT instruction is being executed, the instruction is ignored and not executed until the currently executing instruction completes. When the instruction is ignored, SM699 (Dedicated instruction skip flag) turns on.
- In the following cases, the instruction completes with an error: when there is no free space in the transfer destination; or when b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), but there is not enough free space for storing transfer-target files and a temporary file (same size as transfer-target files) in the transfer destination.
- When the number of files matching the wild card exceeds the upper limit number of transferable files, the instruction will be completed abnormally.
- When the wild card is designated in the file name, the file name in the transfer destination will be in all capital letters.

## Precautions

- If a cable is disconnected, power is shut off, or the CPU module is reset during the file transfer processing, delete unnecessary files (such as a temporary file and undefined files) on the FTP server as needed. Then, transfer files again.
- When b2 (Transfer completion file delete setting) of (s1)+0 is set to 1 (Delete), note the following.

| Item                                                      | Description                                                                                                                   |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| When files in the CPU module are transferred              | Files required for the CPU module to operate are also deleted. If deleted, operations of the CPU module cannot be guaranteed. |
| When wild card characters are used to specify a file name | Required files may be deleted unintentionally.                                                                                |

- When b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), a temporary file of 12 characters (FTPCLI\_I.TMP) will be created in the transfer destination. Therefore, set the folder path so that the total number of characters in the folder path and the temporary file does not exceed the maximum path length supported by the FTP server.
- Do not use any unsupported character(s) in the operand of the SP.FTPPUT instruction. Furthermore, if a file includes any unsupported character(s) in its file name, do not store the file in a folder which is a transfer source of the SP.FTPPUT instruction.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H                      | There is no NULL code (0000H) in each setting area in the device/label memory in device specified by (s2), (s3) and later.                                  |
| 3405H                      | The number of characters in the string specified by (s2) exceeds 255.                                                                                       |
|                            | The number of characters in the path specified by (s2), excluding the file name, exceeds 246 (not including a delimiter).                                   |
|                            | The total number of characters in the strings specified by (s2) (only the file name part, excluding the drive number and folder path) and (s3) exceeds 255. |
|                            | The drive number specified by (s2) is out of range.                                                                                                         |
| 3426H                      | A file name is not specified by (s2).                                                                                                                       |
|                            | The file name that cannot be transferred is specified by (s2).                                                                                              |
|                            | The delimiter used to separate the drive number in (s2) is neither ':' nor '/'.                                                                             |
|                            | Two or more asterisks '*' are used in the file name (before the period) or the extension specified by (s2).                                                 |
|                            | An asterisk '*' and a question mark '?' are used in the file name (before the period) or the extension specified by (s2).                                   |
|                            | Wild card characters, '*' and '?', are used in the string specified by (s3).                                                                                |
| 3430H                      | The SP.FTPPUT instruction was executed without setting FTP client parameters.                                                                               |
| 3582H                      | The SP.FTPPUT instruction is executed in an interrupt program.                                                                                              |

# Retrieving FTP client files

## SP.FTPGET

FX5S

FX5UJ

FX5U

FX5UC

This instruction retrieves files on the FTP server, which are specified by (s2), to the folder path of the CPU module, which is specified by (s3).

## Processing details

- This instruction retrieves files on the FTP server, which are specified by (s2), to the folder path of the CPU module, which is specified by (s3). The CPU module opens a connection with the FTP server set in the module parameters ("FTP Client Settings") at execution of the instruction, and closes a connection after retrieving files. For details on the parameter setting, refer to the following.

### MELSEC iQ-F FX5 User's Manual (Communication)

- The total number of files to be transferred by the SP.FTPGET instruction is stored in (s1)+2, and the number of transferred files is stored in (s1)+3.
- Specify the folder path where the transfer source files are stored on the FTP server, and the file name (including an extension) in (s2) in Unicode string. The maximum number of characters used in a file path is 255. The specified file path shall be a relative path from home directory of the FTP server. Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path or the file name.<sup>\*1</sup>

(1) Use one-byte '\' or '/' as a delimiter of the folder path or file.<sup>\*1</sup>

(2) The specified file name should include an extension.

<sup>\*1</sup> Note that '\' cannot be used as a delimiter for some FTP servers.

- Wild card characters (\*, ?) can be used in the file name or the extension specified in (s2).

| Symbol | Description                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------|
| *      | An asterisk '*' is replaced with any character or string (including none) in a file name.                           |
| ?      | A question mark '?' is replaced with a character (excluding none) in a file name. ('?' can be used multiple times.) |

Wild card characters do not recognize periods.

Using wild card characters in the following ways results in an error.

- Two or more asterisks '\*\*' are used in a file name (before the period) or an extension. (Example: \*abc\*.csv)
- An asterisk '\*' and a question mark '?' are used in a file name (before the period) or an extension. (Example: \*ab?. csv)

When any wild card character is used, the number of files that can be transferred is determined by the total size of the file names of the specified files. The specified files can be transferred when the number of these files and the total size of the file names satisfy the following condition. If a file transfer function instruction is executed without satisfying the following condition, the instruction completes with an error.

$$(F_i + N \cdot M) + 1 < 32768 \text{ [bytes]}$$

N: Total number of files that match the wild card specification  
F<sub>i</sub>: Total size of the file names that match the wild card specification  
M: Specific information size (Fixed value: 6 bytes)

- If an error occurs in any one of the files to be retrieved during execution of the SP.FTPGET instruction, the transfer processing will be stopped upon detection of the error, and the rest of target files will not be transferred.
- Untransferable files will not be transferred even though the wild card specification conditions are satisfied.
- If the number of characters in the file path which includes a file name and an extension exceeds 255, files will not be transferred even though the wild card specification conditions are satisfied.
- If only a file name is specified by (s2), the CPU module directly accesses under the home directory of the FTP server. When specifying only a file name, start with a delimiter. For details, follow the FTP server specifications.
- Specify the folder path of the transfer destination CPU module in (s3) in Unicode string. Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path. The maximum number of characters in the folder path is 247 (246 when a delimiter at the end of the string is omitted). Note that the total number of characters in a folder path (including the delimiter at the end) and the file name specified in (s2) must be within the maximum path length (255 characters) supported by the CPU module. (When the delimiter at the end is omitted, it must not exceed 254 characters.) The delimiter at the end of a string can be omitted. When omitted, '\' is assumed to be set at the end. If a nonexistent folder path is specified, a folder is automatically created by the system at execution of the instruction, and then the processing is performed.

- (1) Drive numbers that can be specified are 2. (LIMELSEC iQ-F FX5 User's Manual (Application))  
 (2) Use one-byte '\' or '/' as a delimiter of the drive number.  
 (3) Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path.  
 (4) The delimiter at the end of string can be omitted.

- If a file with the same name exists in the transfer destination, the file will be overwritten.
- When a file with large size is transferred, the transfer time may be longer. ((Example) Transfer time of 16-MB file with scan time of 5 ms: Approx. 450 sec)
- The execution status and the completion status of the SP.FTPGET instruction can be checked with the completion device (d) and the completion status indication device (d)+1.

| Device                                    | Operation                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d)                     | This device turns on during END processing of the scan where the SP.FTPGET instruction completes, and turns off during the next END processing.                                                                                                                                                                                                                                                                                                                       |
| Completion status indication device (d)+1 | This device turns on or off depending on the completion status of the SP.FTPGET instruction. <ul style="list-style-type: none"> <li>• When completed successfully: The device remains off.</li> <li>• When completed with an error: The device turns on during END processing of the scan where the SP.FTPGET instruction completes, and turns off during the next END processing. In addition, an error code is stored in the device specified by (s1)+1.</li> </ul> |

- The following figure shows the execution timing of the SP.FTPGET instruction.

(1) SM1392 turns on during the END processing after the CPU module is connected to the FTP server.

(2) Values are stored upon completion of the instruction.

(3) When all files have been transferred, SM1392 turns off.

- SM1392 (FTP client connection status) is on while the CPU module is connected to the FTP server, and SM1392 turns off when disconnected.
- SM753 (File access in progress) turns on while the SP.FTPGET instruction is being executed. While SM753 is on, the SP.FTPGET instruction cannot be executed. If executed, no processing is performed.
- If the SP.FTPGET instruction is executed while the SP.FTPPUT or SP.FTPGET instruction is being executed, the instruction is ignored and not executed until the currently executing instruction completes. When the instruction is ignored, SM699 (Dedicated instruction skip flag) turns on.
- In the following cases, the instruction completes with an error: when there is no free space in the transfer destination; or when b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), but there is not enough free space for storing transfer-target files and a temporary file (same size as transfer-target files) in the transfer destination.
- Even though the operating status of the CPU module is switched from RUN to STOP during the file transfer processing, the CPU module continues the processing until completed.

## Precautions

- If a cable is disconnected, power is shut off, or the CPU module is reset during the file transfer processing, transfer files again. In those cases, unnecessary files will be deleted in the following ways.

| Unnecessary file               | Delete operation                                                                                                                        |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Temporary file (FTPCLI_I.TMP)  | A temporary file left in the FTP client will be automatically deleted at the start of next file transfer processing to the same folder. |
| Undefined transfer target file | An undefined transfer target file left in the FTP client will be overwritten during next file transfer processing to the same file.     |

- When a file with the same name has already existed in the transfer destination and its access is restricted by the file password function, the SP.FTPGET instruction completes with an error.
- When b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), set the maximum number of characters in the folder path of the CPU module to 243 (242 when a delimiter at the end of the string is omitted). Since a temporary file of 12 characters (FTPCLI\_I.TMP) is created in the transfer destination, set the folder path so that the total number of characters in the folder path and the temporary file does not exceed the maximum path length (255 characters) supported by the CPU module.
- Do not use unsupported characters for the operands of the SP.FTPGET instruction. Do not store any file with a file name containing unsupported characters in the source folder to transfer the SP.FTPGET instruction.

## Operation error

| Error code (SD0) | Description                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------|
| 2820H            | There is no NULL code (0000H) in each setting area in the device/label memory in device specified by (s2), (s3) and later. |
| 3405H            | The number of characters in the string specified by (s2) exceeds 255.                                                      |
|                  | The number of characters in the path specified by (s2), excluding the file name, exceeds 246 (not including a delimiter).  |
|                  | The total number of characters in the strings specified by (s3) and (s2) (only the file name part) exceeds 255.            |
|                  | The drive number specified by (s3) is out of range.                                                                        |
| 3426H            | A file name is not specified by (s2).                                                                                      |
|                  | The file name that cannot be transferred is specified by (s2).                                                             |
|                  | The delimiter used to separate the drive number in (s3) is neither ':' nor '/'.                                            |
|                  | Two or more asterisks '*' are used in the file name (before the period) or the extension specified by (s2).                |
|                  | An asterisk '*' and a question mark '?' are used in the file name (before the period) or the extension specified by (s2).  |
|                  | Wild card characters, '*' and '?', are used in the string specified by (s3).                                               |
| 3430H            | The SP.FTPGET instruction was executed without setting FTP client parameters.                                              |
| 3582H            | The SP.FTPGET instruction is executed in an interrupt program.                                                             |

# 13.6 Ethernet Module

## Opening a connection

### GP.OPEN

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction opens a connection.

| (s2)+7 to<br>(s2)+9 | —                                       | Use prohibited                                                                                                                                                                                                                                                                                                                                                                                                                              | —                                                                                       | System               |

\*1 User: Data to be set before the execution of the instruction. System: The Ethernet module stores the execution result of the instruction.

\*2 When Unpassive open is selected, the target device IP address and target device port number are ignored.

\*3 Of the host station port numbers, 1 to 1023 (0001H to 03FFH) are generally reserved port numbers and 61440 to 65534 (F000H to FFFE<sup>H</sup>) are used by other communication functions. Thus, using 1024 to 5548 and 5570 to 61439 (0400H to 15ACH and 15C2H to EFFFH) as the port numbers is recommended. Do not specify 5549 to 5569 (15ADH to 15C1H) since they are used by the system.

## Processing details

This instruction opens the connection specified by (s1).

The setting value used by the open processing is selected by (s2)+0.

The completion of the GP.OPEN instruction can be checked using the completion devices (d)+0 and (d)+1.

- Completion device (d)+0: Turns ON during the END processing for the scan in which the GP.OPEN instruction is completed, and turns OFF during the next END processing.
- Completion device (d)+1: Turns ON or OFF depending on the status of when the GP.OPEN instruction is completed.

| Status                       | Description                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                               |
| When completed with an error | The device turns ON during the END processing for the scan in which the GP.OPEN instruction is completed, and turns OFF during the next END processing. |

The connection in which no protocol is set with the parameter can be opened and used. In this case, specify 8000H in (s2)+0 and the contents of the open processing in (s2)+2 to (s2)+6.

## Operation error

\*1 System: The Ethernet module stores the execution result of the instruction.

## Processing details

This instruction closes the connection specified by (s1). (Connection disconnection)

The completion of the GP.CLOSE instruction can be checked using the completion devices (d)+0 and (d)+1.

- Completion device (d)+0: Turns ON during the END processing for the scan in which the GP.CLOSE instruction is completed, and turns OFF during the next END processing.
- Completion device (d)+1: Turns ON or OFF depending on the status when the GP.CLOSE instruction is completed.

| Status                       | Description                                                                                                                                              |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                |
| When completed with an error | The device turns ON during the END processing for the scan in which the GP.CLOSE instruction is completed, and turns OFF during the next END processing. |

### Point

Do not execute the GP.CLOSE instruction when Passive open is selected. Since the open completion signal and open request signal of the corresponding connection turn OFF and close processing is executed, the communication is disabled.

| (d1)+0           | Receive data length | The data length of the data read from the socket communication receive data area is stored. (Number of bytes)                                                                                                                                                                                             | 0 to 2046     | System   |
| (d1)+1 to (d1)+n | Receive data        | The data read from the socket communication receive data area is sequentially stored.                                                                                                                                                                                                                     | —             | System   |

\*1 System: The Ethernet module stores the execution result of the instruction.

### Point

- When the GP.SOCRCV instruction is executed, reading data from the socket communication receive data area is executed with the END processing. Thus, executing the GP.SOCRCV instruction extends the scan time.
- When the data of odd-number of bytes is received, invalid data is stored in the higher byte of the device where the last receive data is stored.

## Processing details

In the END processing after the execution of the GP.SOCRCV instruction, the receive data of the connection specified by (s1) is read from the socket communication receive data area.

The completion of the GP.SOCRCV instruction can be checked using the completion devices (d2)+0 and (d2)+1.

- Completion device (d2)+0: Turns ON during the END processing for the scan in which the GP.SOCRCV instruction is completed, and turns OFF during the next END processing.
- Completion device (d2)+1: Turns ON or OFF depending on the status when the GP.SOCRCV instruction is completed.

| Status                       | Description                                                                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                 |
| When completed with an error | The device turns ON during the END processing for the scan in which the GP.SOCRCV instruction is completed, and turns OFF during the next END processing. |

## Operation error

| Error code ((s2)+1) | Description                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| C000H to CFFFH      | Refer to  MELSEC iQ-F FX5 Ethernet Module User's Manual.<br>Refer to  MELSEC iQ-F FX5 EtherNet/IP Module User's Manual. |

# Sending data

## GP.SOCSND

\*1 User: Data to be set before the execution of the instruction. System: The Ethernet module stores the execution result of the instruction.

### Point

When TCP is used, specify send data length that is smaller than the maximum window size of the target device (Receive data buffer of TCP). Data whose size exceeds the maximum window size of the target device cannot be sent.

## Processing details

This instruction send the data set by (s3) to the target device of the connection specified by (s1).

The completion of the GP.SOCSND instruction can be checked using the completion devices (d)+0 and (d)+1.

- Completion device (d)+0: Turns ON during the END processing for the scan in which the GP.SOCSND instruction is completed, and turns OFF during the next END processing.
- Completion device (d)+1: Turns ON or OFF depending on the status when the GP.SOCSND instruction is completed.

| Status                       | Description                                                                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| When completed normally      | The device does not change (remains OFF).                                                                                                                 |
| When completed with an error | The device turns ON during the END processing for the scan in which the GP.SOCSND instruction is completed, and turns OFF during the next END processing. |

## Operation error

| Error code ((s2)+1) | Description                                                                                                             |

# 14 CC-Link IE TSN INSTRUCTION

## 14.1 Own Station Number/IP Address Setting

### G(P).UINI

These instructions specify the station number and IP address to the own station which they are not set yet.

| Ladder | ST                                                          |
|--------|-------------------------------------------------------------|
|        | <pre>ENO:=G_UINI(EN,Un,s,d); ENO:=GP_UINI(EN,Un,s,d);</pre> |

### FBD/LD

("G\_UINI", "GP\_UINI" enters □.)

14

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                                                                                                                      | Range                  | Data type              | Data type (label)                       |

### Point

- The G(P).UINI instruction can be executed only once.
- If the G(P).UINI instruction is executed after the station number and IP address have been determined, it will complete with an error.
- If the G(P).UINI instruction completes with an error before the station number and IP address are determined, take corrective action to correct the error content before retrying to execute the instruction.
- Set the subnet mask and default gateway using the engineering tool as necessary.

## Processing details

- Sets the station number and IP address for the own station.

[Own station]

- The execution status and the completion status of the G(P).UINI instruction can be checked with the completion device (d) and the completion status indication device (d)+1.

## Precautions

Do not set the broadcast address and the reserved address to the IP address ((s)+4, 5). If set, the instruction may not be executed properly.

## Operation error

## 14.2 Sending an SLMP Frame

### G(P).SLMPSND

FX5S

FX5UJ

FX5U

FX5UC

These instructions send/receive an SLMP message to the SLMP-compatible device on the same network.

\*1 If (s1)+0 is set to "0: Without arrival check", receive data is not set. Set 0 in (s1)+0 in the following cases:

- When a command that does not return a response message is used
- When a response message is not referred to

\*2 Set the serial numbers when sending multiple request messages to the same SLMP-compatible device.

Serial numbers to be set are automatically numbered by the system.

\*3 If an error was detected, the number of resends performed (result) between error detection and resend stop is stored.

## Request data

## Response data

| Device           | Item                 | Description                                                                                                                                  | Setting range | Set by |
|------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| (d1)+0           | Response data length | The data length from the end code to the response data is stored. (In units of bytes)                                                        | —             | System |
| (d1)+1           | End code             | The result of command processing is stored. In normal end, 0 is stored. In abnormal end, an error code set by the target device is stored.*1 | —             | System |
| (d1)+2 to (d1)+n | Response data        | Execution results for the request data are set.<br>(Some commands do not return response data.)                                              | —*2           | System |

\*1 For the set error code and the corresponding error description, check the specifications of the target device.

\*2 For details on the response data, refer to the  MELSEC iQ-F FX5 User's Manual (Communication).

## Processing details

- This instruction sends the request data in the device specified by (s2) and later to the external device specified by the target device IP address in the control data. When a response message is received from the target device, it is stored in the device specified by (d1).
- The SLMPSEND instruction uses the UDP/IP communication methods in binary code.
- The completion status of the SLMPSEND instruction can be checked with the completion device (d2) and the completion status indication device (d2)+1.

| Device                                     | Operation                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d2)                     | This device turns on in the END processing of the scan where the SLMPSEND instruction completes, and turns off in the next END processing.                                                                                                                                                                                 |
| Completion status indication device (d2)+1 | This device turns on or off depending on the completion status of the SLMPSEND instruction.<br>When completed normally: The device remains off.<br>When completed with an error: The device turns on in the END processing of the scan where the SLMPSEND instruction completes, and turns off in the next END processing. |

- When executing multiple SLMPSEND instructions concurrently, be careful not to overlap the channels of the SLMPSEND instructions. Multiple SLMPSEND instructions specifying the same channels cannot be used concurrently.
- When the execution conditions of the SLMPSEND instructions in the same channel are satisfied in the same sequence scan, only the SLMPSEND instruction that has been executed first is enabled and the subsequent SLMPSEND instructions are not executed. In addition, any subsequent SLMPSEND instruction of the same channel setting as the SLMPSEND instruction being executed is not executed.
- Specify the arrival monitoring time ((s1)+11) of the control data and monitoring timer ((s2)+1) of the request frame so that the arrival monitoring time  $\geq$  monitoring timer.

- (1) Request message  
 (2) Processing request from target device to request destination  
 (3) Processing response from request destination to target device  
 (4) Response message

## ■Message format (3E/4E frame)

The following figures show the request data of 3E/4E frame and the response data in normal/abnormal end.

### ● Request message

### ● Response message (in normal end)

### ● Response message (in abnormal end)

The network number, station number, request destination module I/O number, and multidrop station number are stored to the information of the error responding station.

## ■ Message format (station number extension frame)

The following figures show the request data of station number extension frame and the response data in normal/abnormal end.

### ● Request message

### ● Response message (in normal end)

### ● Response message (in abnormal end)

The network number, station number, request destination module I/O number, multidrop station number, 00 (fixed value), and extension station number are stored to the information of the error responding station.

**Ex.**

When sending "Read (command: 0401H)" (reading in units of words) which reads the value in D100 to D102

- The following example shows that request data is stored in (s2)+2 and later (3E/4E frame).

- The following example shows that response data is stored in (d1)+2 and later (3E/4E frame).

- The following example shows that request data is stored in (s2)+2 and later (station number extension frame).

- The following example shows that response data is stored in (d1)+2 and later (station number extension frame).

## Operation error

| Error code ((s1)+1) | Description                                                                |
|---------------------|----------------------------------------------------------------------------|
| 1000H to 3FFFH      | Refer to MELSEC iQ-F FX5 CC-Link IE TSN Master/Local Module User's Manual. |
| 4000H to 4FFFH      | Refer to MELSEC iQ-F FX5 User's Manual (Application).                      |
| D000H to DFFFH      | Refer to MELSEC iQ-F FX5 CC-Link IE TSN Master/Local Module User's Manual. |

---

The SLMPSEND instruction is successfully completed even if the target device returns an abnormal response. When the SLMPSEND instruction is completed successfully, the response is whether normal or abnormal can be identified by the end code of the response frame.

When an abnormal response is returned, check the manual of the SLMP-compatible device being used and take corrective action.

---

# 15 CC-Link IE Field Network INSTRUCTION

## 15.1 Setting parameters

### G(P).CCPASET

**FX5S** **FX5UJ** **FX5U** **FX5UC**

Set the parameters to the FX5-CCLIEF.

## Processing details

- Set the station number to the intelligent device station.

[Own station]

- The execution status and the completion status of the G(P).UINI instruction can be checked with the completion device (d) and the completion status indication device (d)+1.

| Device                                    | Operation                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Completion device (d)                     | The device turns on during the END processing for the scan in which the G(P).UINI instruction is completed, and turns off during the next END processing.                                                                                                                                                                                                    |
| Completion status indication device (d)+1 | The device turns on or off depending on the completion status of the G(P).UINI instruction.<br>When completed normally: The device does not change (remains off).<br>When completed with an error: The device turns on during the END processing for the scan in which the G(P).UINI instruction is completed, and turns off during the next END processing. |

- The following figure shows the operation at completion of the G(P).UINI instruction.

When completed normally

When completed with an error

## Precautions

- The station number set by the G(P).UINI instruction is cleared when the FX5 CPU module is powered off and on or reset.
- The G(P).UINI can be executed on the intelligent device station with no station number setting.
- If the station number set by the G(P).UINI instruction is already used for another station, the instruction is completed with an error. Set a unique station number. Note that such error cannot be detected before data link start (e.g. absence of the master station).

## Operation error

| Error code ((s)+1) | Description                                                                              |

# 16 HIGH-SPEED COUNTER INSTRUCTION

## 16.1 High-speed Processing Instruction

### Setting 32-bit data comparison

#### DHSCS

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction compares the value counted by a high-speed counter with a specified value, and immediately sets a bit device if the two values are equivalent to each other.

The high-speed pulse input/output module is not supported.

| Ladder diagram                                                                    | Structured text*1                                     |
|-----------------------------------------------------------------------------------|-------------------------------------------------------|
|  | ENO:=DHSCS(EN,s1,s2,d);<br>ENO:=DHSCS_I(EN,s1,s2,Pn); |

#### FBD/LD\*1

\*1 When the interrupt pointer (I) is specified in operand (d) by ST language and the FBD/LD language, use the DHSCS\_I instruction.

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                                                                              | Range                      | Data type            | Data type (label) |
|---------|--------------------------------------------------------------------------------------------------------------------------|----------------------------|----------------------|-------------------|
| (s1)    | Data to be compared with the current value of a high-speed counter or word device number storing the data to be compared | -2147483648 to +2147483647 | 32-bit signed binary | ANY32             |

| (s1)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —          |
| (s2)    | ○                           | ○                         | ○     | ○ | ○*1         | ○  | ○                      | ○        | — | —  | —          |
| (d)     | ○                           | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○*2        |

\*1 Enable the FX3 compatible function, and specify a device between LC35 and 55 that is designated as an FX3 compatible high-speed counter.

For FX3 compatible function, refer to MELSEC iQ-F FX5 User's Manual (Application).

\*2 I16 to I23 can be used.

## Processing details

- When the current value of a high-speed counter of the channel specified in (s2) becomes the comparison value (s1) (for example, when the current value changes from "199" to "200" or from "201" to "200" if the comparison value is K200), the bit device (d) is set to ON regardless of the scan time. In this instruction, the comparison processing is executed after the count processing in the high-speed counter. For details, refer to MELSEC iQ-F FX5 User's Manual (Application).

### Point

Use DHSCS if the output should be given when the counting result becomes equivalent to the comparison value regardless of the scan time of the CPU module.

When the number of instructions that can be simultaneously used is exceeded, use a general-purpose comparison instruction.

If using the high-speed comparison match interrupt, the corresponding interrupt programs can be executed by setting the interrupt pointers (I16 to I23) to (d) as shown below.

A: Main routine program

B: I16 Interrupt Program

(1): Start the high-speed counter CH1.

(2): When the current value of the high-speed counter CH1 reaches 1000, the interrupt program (I16) is executed.

## Precautions

The value specified in (s2) should only be the channel of high-speed counter number (1 to 8) set by the parameter.

An operation error occurs in the following cases.

- When a channel which is not set by the parameter or a value other than K1 to 8 is specified
- When an LC device number which is not set by the parameter is specified

For other precautions, refer to MELSEC iQ-F FX5 User's Manual (Application).

## Program example

- Parameter

When using the data comparison by the high-speed counter, set "Use/Do Not Use Counter" of CH1 to "Enable" with the following parameter.

Navigation window ⇒ [Parameter] ⇒ Module model name ⇒ [Module Parameter] ⇒ [High Speed I/O] ⇒ "Input Function" ⇒ "High Speed Counter" ⇒ "Detailed Setting" ⇒ "Basic Settings"

- Program

In the program example shown below, with regard to the current value of a counter, different outputs (Y10 and Y11) are arbitrarily set to ON by two values.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                                                       |

# Reset 32-bit data comparison

## DHSCR

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

This instruction compares the value counted by a high-speed counter with a specified value, and immediately resets a bit device if the two values are equivalent to each other, or resets the high speed counter.

The high-speed pulse input/output module is not supported.

| Ladder diagram | Structured text                    |

\*1 Enable the FX3 compatible function, and specify a device between LC35 and 55 that is designated as an FX3 compatible high-speed counter.

For FX3 compatible function, refer to MELSEC iQ-F FX5 User's Manual (Application).

## Processing details

- When the current value of a high-speed counter of the channel specified in (s2) becomes the comparison value (s1) (for example, when the current value changes from "199" to "200" or from "201" to "200" if the comparison value is K200), the bit device (d) is reset to OFF regardless of the scan time. For details, refer to MELSEC iQ-F FX5 User's Manual (Application).

- The same channel number as (s2) or the LC device is specified in (d), (d) is reset to OFF by itself.

Example of specifying the same channel number as (s2) in (d)

When the current value of the high-speed counter of CH1 becomes 400, the current value is overwritten to the preset value.

[Program example]

Example of specifying the LC device in (d)

When the current value of LC55, the high-speed counter of CH4 with 2-phase 2-input (1-multiplication/4-multiplication) becomes 300, the output contact of LC55 turns ON. When the current value of LC55 becomes 400, the current value is cleared to 0 and the output contact turns OFF.

[Program example]

### Point

Use DHSCR if the output should be given when the counting result becomes equivalent to the comparison value regardless of the scan time of the CPU module.

When the number of instructions that can be simultaneously used is exceeded, use a general-purpose comparison instruction.

## Precautions

The value specified in (s2) should only be the channel of high-speed counter number (1 to 8) set by the parameter.

An operation error occurs in the following cases.

- When a channel which is not set by the parameter or a value other than K1 to 8 is specified
- When an LC device number which is not set by the parameter is specified

For other precautions, refer to MELSEC iQ-F FX5 User's Manual (Application).

\*1 Enable the FX3 compatible function, and specify a device between LC35 and 55 that is designated as an FX3 compatible high-speed counter.

For FX3 compatible function, refer to [MELSEC iQ-F FX5 User's Manual \(Application\)](#).

## Processing details

- The current value of a high-speed counter specified in (s3) is compared with two comparison points (comparison value 1 and comparison value 2). Based on the zone comparison result, "smaller than the lower comparison value", "inside the comparison zone" or "larger than the upper comparison value", one among (d), (d)+1 and (d)+2 is set to ON regardless of the scan time. For details, refer to MELSEC iQ-F FX5 User's Manual (Application).

- Make sure that the comparison value 1 and the comparison value 2 have the following relationship: [Comparison value 1] ≤ [Comparison value 2]. When the setting differs from the above, an operation error occurs and the DHSZ instruction will not perform any operation.
- When the current value of the high-speed counter CH1 changes (counts) as shown below, the comparison result is turn on to one of the outputs Y0, Y1 or Y2.

| Comparison pattern | Current value of CH1 (s3) | Change of output contact (Y) |        |        |
|--------------------|---------------------------|------------------------------|--------|--------|
|                    |                           | Y0                           | Y1     | Y2     |
| (s1)>(s3)          | 1000>(s3)                 | ON                           | OFF    | OFF    |
|                    | 999→1000                  | ON→OFF                       | OFF→ON | OFF    |
|                    | 1000→999                  | OFF→ON                       | ON→OFF | OFF    |
| (s1) ≤ (s3) ≤ (s2) | 999→1000                  | ON→OFF                       | OFF→ON | OFF    |
|                    | 1000→999                  | OFF→ON                       | ON→OFF | OFF    |
|                    | 1000 ≤ (s3) ≤ 2000        | OFF                          | ON     | OFF    |
|                    | 2000→2001                 | OFF                          | ON→OFF | OFF→ON |
|                    | 2001→2000                 | OFF                          | OFF→ON | ON→OFF |
| (s3)>(s2)          | 2000→2001                 | OFF                          | ON→OFF | OFF→ON |
|                    | 2001→2000                 | OFF                          | OFF→ON | ON→OFF |
|                    | (s3)>2000                 | OFF                          | OFF    | ON     |

### Point

It is used when the output should be given when the counting result becomes equivalent to the comparison value regardless of the scan time of the CPU module.

When the number of instructions that can be simultaneously used is exceeded, use a general-purpose comparison instruction.

## Precautions

An operation error occurs in the following cases.

- When a channel which is not set to (s3) by the parameter or a value other than K1 to 8 is specified
- When an LC device number which is not set by the parameter is specified

Three devices are occupied from the device specified in (d). Make sure that these devices are not used in other controls.

When designating a Y device, do not set a device that crosses over a module or a device No. that is a multiple of 16

### Ex.

Example: Designating Y36 or Y37 when using FX5U-64M□.

For other precautions, refer to MELSEC iQ-F FX5 User's Manual (Application).

## Program example

### • Parameter

When using the data band comparison by the high-speed counter, set "Use/Do Not Use Counter" of CH1 to "Enable" with the following parameter.

Navigation window ⇒ [Parameter] ⇒ Module model name ⇒ [Module Parameter] ⇒ [High Speed I/O] ⇒ "Input Function" ⇒ "High Speed Counter" ⇒ "Detailed Setting" ⇒ "Basic Settings"

### • Program

In the program shown below, the data range (K1000 to K1200) specified for the current value of the counter is compared, and the output (Y10 to Y12) is set (ON) according to the comparison results.

16

## Operation error

## Processing details

Specify the number of the function to be started or stopped in (s1), the bit of the channel to be started in (s2), and the bit of the channel to be stopped in (s3).

The following table shows the function numbers which can be specified in (s1).

### ■Function number

| Function number     | Function name                                                             |
|---------------------|---------------------------------------------------------------------------|
| K0                  | High-speed counter                                                        |
| K10 <sup>*1</sup>   | Pulse density/rotation speed measurement                                  |
| K20 <sup>*1</sup>   | High-speed comparison table (CPU module)                                  |
| K21 <sup>*1</sup>   | High-speed comparison table (first high-speed pulse input/output module)  |
| K22 <sup>*1</sup>   | High-speed comparison table (second high-speed pulse input/output module) |
| K23 <sup>*1</sup>   | High-speed comparison table (third high-speed pulse input/output module)  |
| K24 <sup>*1</sup>   | High-speed comparison table (fourth high-speed pulse input/output module) |
| K30 <sup>*1*2</sup> | Multi-output high-speed comparison table                                  |
| K40                 | Pulse width measurement                                                   |
| K50                 | PWM                                                                       |

\*1 When high-speed counter (function number: K0) is stopped during function operation, the function continues to operate, but nothing will be processed.

\*2 When multi-output high-speed comparison table (function number: K30) is stopped, high-speed counter of the same channel is also stopped.

The following table shows the values which can be specified in (s2) and (s3) for each function number.

#### • Function number K0

The counting start and stop of a high-speed counter can be controlled for each channel of high-speed counter.

CH1 to CH8 are for the CPU module, and CH9 to CH16 are for the high-speed pulse input/output module.

| Bit position |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14  | b13  | b12  | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| CH16         | CH15 | CH14 | CH13 | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

#### Ex.

To start CH3, set 04H in (s2). To stop it, set 04H in (s3).

To start CH1, CH4, and CH5, set 19H in (s2). To stop them, set 19H in (s3).

To start CH1 and CH4 and to stop CH5, set 09H in (s2) and set 10H in (s3).

#### • Function number K10

The measuring start and stop of the pulse density (rotation speed measurement) can be controlled for each channel of the high-speed counter.

| Bit position |     |     |     |     |     |    |    |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|-----|-----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            |     |     |     |     |     |    |    | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

#### • Function number K20 to K24

Set the value to turn on the bit of the high-speed comparison table number which is to be started or stopped.

In the case of the CPU module (K20), b0 to b15 can be used.

In the case of the high-speed pulse input/output module (K21 to K24), b0 to b14 can be used.

| Bit position |     |     |     |     |     |    |    |    |    |    |    |    |    |    |    |
|--------------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| b15          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| 16           | 15  | 14  | 13  | 12  | 11  | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  |

- Function number K30

For the multi-output high-speed comparison table, specification of a channel is not required. To start the multi-output high-speed comparison table, set 01H in (s2). To stop it, set 01H in (s3).

| Bit position |     |     |     |     |     |    |    |    |    |    |    |    |    |    |       |
|--------------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|-------|
| b15          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0    |
| —            |     |     |     |     |     |    |    |    |    |    |    |    |    |    | Valid |

- Function numbers K40 and K50

The measuring start and stop of pulse width measurement and PWM can be controlled for each channel.

CH1 to CH4 are for the CPU module, and CH5 to CH12 are for the high-speed pulse input/output module.

| Bit position |     |     |     |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            |     |     |     | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

## Precautions

- Do not specify channel numbers of the high-speed pulse input/output module in a program with interrupt priority set to "1".
- When values that turn on the same channel are set for start and stop, the stop operation is prioritized.
- If there is a channel where an error occurs (error code: 3781H) when the high-speed counter (function number: K0) is executed by the HIOEN instruction, the counter can no longer be started/stopped for the applicable channel and subsequent channels.
- When the high-speed comparison table (function number: K20) is used with the HIOEN instruction, the total number of high-speed comparisons, including the DHSCS instruction, DHSCR instruction, DHSZ instruction, and interrupt input of built-in positioning, must be 32 or less.
- When using the high-speed comparison table (function numbers: K21 to K24) with the HIOEN instruction, set the number of high-speed comparisons used within the same high-speed pulse input/output module to 15 times or less.
- For the high-speed comparison table numbers and total number of high-speed comparisons, refer to  Page 1454 Added and Changed Functions.
- To start the high-speed comparison table (function numbers: K20 to K24) or the multi-output high-speed comparison table (function number: K30), the high-speed counter must be started using the HIOEN instruction in advance.
- The high-speed input/output instructions operate according to the following parameters.

| Function number | Function specified by the HIOEN instruction                               | Parameter setting                                                                     |
|-----------------|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| K0              | High-speed counter                                                        | Channel setting of the high-speed counter                                             |
| K10             | Pulse density (rotation speed measurement)                                | Channel setting of the pulse density/rotation speed measurement<br>High-speed counter |
| K20             | High-speed comparison table (CPU module)                                  | Output setting of the high-speed counter                                              |
| K21             | High-speed comparison table (first high-speed pulse input/output module)  | Output setting of the high-speed counter                                              |
| K22             | High-speed comparison table (second high-speed pulse input/output module) | Output setting of the high-speed counter                                              |
| K23             | High-speed comparison table (third high-speed pulse input/output module)  | Output setting of the high-speed counter                                              |
| K24             | High-speed comparison table (fourth high-speed pulse input/output module) | Output setting of the high-speed counter                                              |
| K30             | Multi-output high-speed comparison table                                  | Output setting of the high-speed counter                                              |
| K40             | Pulse width measurement                                                   | Channel setting of the pulse width measurement                                        |
| K50             | PWM                                                                       | Channel setting of PWM                                                                |

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 1810H                      | The channel specified by instructions using communication functions or built-in I/O is already used by other instructions.     |
| 2801H                      | The channel number of a module that does not exist is specified.                                                               |
| 3056H                      | Timeout occurred while communicating with the target modules during execution of the instruction.                              |
| 3060H                      | Signal error was detected while accessing the target modules during execution of the instruction.                              |
| 3405H                      | An invalid function number is specified in (s).                                                                                |
| 3580H                      | An instruction that cannot be used in an interrupt program is used.                                                            |
| 3600H                      | A channel number which is not selected in the parameter setting is executed.                                                   |
| 3781H                      | Ring length $\leq$ preset value is specified and executed in channel for which ring length is set and preset input is enabled. |

# Start/stop of the 32-bit data high-speed I/O function

## DHIOEN(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions control the start and stop operations of a high-speed I/O function.

| Ladder diagram                                                                    | Structured text                                         |

## Processing details

Specify the number of the function to be started or stopped in (s1), the bit of the channel to be started in (s2), and the bit of the channel to be stopped in (s3).

The following table shows the function numbers which can be specified in (s1).

### ■Function number

| Function number     | Function name                                                             |
|---------------------|---------------------------------------------------------------------------|
| K0                  | High-speed counter                                                        |
| K10 <sup>*1</sup>   | Pulse density/rotation speed measurement                                  |
| K20 <sup>*1</sup>   | High-speed comparison table (CPU module)                                  |
| K21                 | High-speed comparison table (first high-speed pulse input/output module)  |
| K22                 | High-speed comparison table (second high-speed pulse input/output module) |
| K23                 | High-speed comparison table (third high-speed pulse input/output module)  |
| K24                 | High-speed comparison table (fourth high-speed pulse input/output module) |
| K30 <sup>*1*2</sup> | Multi-output high-speed comparison table                                  |
| K40                 | Pulse width measurement                                                   |
| K50                 | PWM                                                                       |

\*1 When high-speed counter (function number: K0) is stopped during function operation, the function continues to operate, but nothing will be processed.

\*2 When multi-output high-speed comparison table (function number: K30) is stopped, high-speed counter of the same channel is also stopped.

The following table shows the values which can be specified in (s2) and (s3) for each function number.

#### • Function number K0

The counting start and stop of a high-speed counter can be controlled for each channel of high-speed counter.

CH1 to CH8 are for the CPU module, and CH9 to CH16 are for the high-speed pulse input/output module.

| Bit position |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14  | b13  | b12  | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| CH16         | CH15 | CH14 | CH13 | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

#### Ex.

To start CH3, set 04H in (s2). To stop it, set 04H in (s3).

To start CH1, CH4, and CH5, set 19H in (s2). To stop it, set 19H in (s3).

To start CH1 and CH4 and to stop CH5, set 09H in (s2) and set 10H in (s3).

#### • Function number K10

The measuring start and stop of the pulse density (rotation speed measurement) can be controlled for each channel of the high-speed counter.

| Bit position |     |     |     |     |     |    |    |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|-----|-----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            |     |     |     |     |     |    |    | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

#### • Function number K20 to K24

Set the value to turn on the bit of the high-speed comparison table number which is to be started or stopped.

In the case of the CPU module (K20), b0 to b31 can be used.

In the case of the high-speed pulse input/output module (K21 to K24), b0 to b14 can be used.

| Low-order bit position |     |     |     |     |     |    |    |    |    |    |    |    |    |    |    |
|------------------------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| b15                    | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| 16                     | 15  | 14  | 13  | 12  | 11  | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  |

| High-order bit position |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b31                     | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| 32                      | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  |

- Function number K30

For the multi-output high-speed comparison table, specification of a channel is not required. To start the multi-output high-speed comparison table, set 01H in (s2). To stop it, set 01H in (s3).

| Bit position |     |     |     |     |     |    |    |    |    |    |    |    |    |    |       |
|--------------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|-------|
| b15          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0    |
| —            |     |     |     |     |     |    |    |    |    |    |    |    |    |    | Valid |

- Function numbers K40 and K50

The measuring start and stop of pulse width measurement and PWM can be controlled for each channel.

CH1 to CH4 are for the CPU module, and CH5 to CH12 are for the high-speed pulse input/output module.

| Bit position |     |     |     |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            |     |     |     | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

## Precautions

- Do not specify channel numbers of the high-speed pulse input/output module in a program with interrupt priority set to "1".
- When values that turn on the same channel are set for start and stop, the stop operation is prioritized.
- If there is a channel where an error occurs (error code: 3781H) when the high-speed counter (function number: K0) is executed by the DHIOEN instruction, the counter can no longer be started/stopped for the applicable channel and subsequent channels.
- When the high-speed comparison table (function number: K20) is used with the DHIOEN instruction, the total number of high-speed comparisons, including the DHSCS instruction, DHSCR instruction, DHSZ instruction, and interrupt input of built-in positioning, must be 32 or less.
- When using the high-speed comparison table (function numbers: K21 to K24) with the DHIOEN instruction, set the number of high-speed comparisons used within the same high-speed pulse input/output module to 15 times or less.
- For the high-speed comparison table numbers and total number of high-speed comparisons, refer to  Page 1454 Added and Changed Functions.
- To start the high-speed comparison table (function numbers: K20 to K24) or the multi-output high-speed comparison table (function number: K30), the high-speed counter must be started using the DHIOEN instruction in advance.
- The high-speed input/output instructions operate according to the following parameters.

| Function number | Function specified by the DHIOEN instruction                              | Parameter setting                                                                     |
|-----------------|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| K0              | High-speed counter                                                        | Channel setting of the high-speed counter                                             |
| K10             | Pulse density (rotation speed measurement)                                | Channel setting of the pulse density/rotation speed measurement<br>High-speed counter |
| K20             | High-speed comparison table (CPU module)                                  | Output setting of the high-speed counter                                              |
| K21             | High-speed comparison table (first high-speed pulse input/output module)  | Output setting of the high-speed counter                                              |
| K22             | High-speed comparison table (second high-speed pulse input/output module) | Output setting of the high-speed counter                                              |
| K23             | High-speed comparison table (third high-speed pulse input/output module)  | Output setting of the high-speed counter                                              |
| K24             | High-speed comparison table (fourth high-speed pulse input/output module) | Output setting of the high-speed counter                                              |
| K30             | Multi-output high-speed comparison table                                  | Output setting of the high-speed counter                                              |
| K40             | Pulse width measurement                                                   | Channel setting of the pulse width measurement                                        |
| K50             | PWM                                                                       | Channel setting of PWM                                                                |

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 1810H                      | The channel specified by instructions using communication functions or built-in I/O is already used by other instructions.     |
| 2801H                      | The channel number of a module that does not exist is specified.                                                               |
| 3056H                      | Timeout occurred while communicating with the target modules during execution of the instruction.                              |
| 3060H                      | Signal error was detected while accessing the target modules during execution of the instruction.                              |
| 3405H                      | An invalid function number is specified in (s).                                                                                |
| 3580H                      | An instruction that cannot be used in an interrupt program is used.                                                            |
| 3600H                      | A channel number which is not selected in the parameter setting is executed.                                                   |
| 3781H                      | Ring length $\leq$ preset value is specified and executed in channel for which ring length is set and preset input is enabled. |

# 16.2 High-speed Current Value Transfer Instruction

## High-speed current value transfer of 16-bit data

### HCMOV(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions read and write (updates) special register for high-speed counter, pulse width measurement, PWM, and positioning.

| Ladder diagram                                                                    | Structured text                                 |

## Processing details

These instructions transfer the data in the device specified by (s) to the device specified by (d). At this time, if the value of (n) is K0, the value of (s) is not cleared. If the value of (n) is K1, the value of (s) is cleared to "0" after the transfer. The value is cleared only for the SD8099 special device supporting high-speed transfer.

### Point

When (s) is a device supporting high-speed transfer

- When the HCMOV instruction is executed, the latest value is acquired such as the current value of a high-speed counter and transferred to (d).

When (d) is a device supporting high-speed transfer

- When the HCMOV instruction is executed, value such as the current value of a high-speed counter is changed.

## ■Effect of HCMOV instruction

- By using both input interrupt and HCMOV instruction, the current value of a high-speed counter can be received at the rising edge or falling edge of an external input.
- When HCMOV instruction is used just before a comparison instruction (CMP, ZCP or comparison contact instruction), the latest value of the high-speed counter is used in comparison.

## Precautions

- When it is necessary to execute comparison and outputting as soon as the current value of a high-speed counter changes, use the high-speed comparison table, multi-output high-speed comparison table, or one of the DHSCS, DHSCR, and DHSZ instructions.
- If 32-bit binary data special device which supports the high-speed transfer (such as the current value of a high-speed counter) is read using the HCMOV instruction, the operation is the same as that when the MOV instruction is used.
- Do not overwrite the current value of a high-speed counter using the HCMOV instruction while executing the pulse density (rotation speed measurement) or the SPD instruction.
- If (s) is SD8099, and the (n) value is K1, SD8099 is cleared at the timing the instruction is executed (after the SD8099 current value is transferred). Do not clear the SD8099 current value with an application instruction such as a MOV instruction, which is affected by the scan.

### Point

The HCMOV instruction is mainly used to read the current value of the high-speed counter/pulse width measurement and change the current address (in the user units) or the current address (in the pulse unit) of positioning.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                             |

## Processing details

These instructions transfer the data in the device specified by (s) to the device specified by (d). At this time, if the value of (n) is K0, the value of (s) is not cleared. If the value of (n) is K1, the value of (s) is cleared to "0" after the transfer. The value is cleared only for SD devices for the current value of high-speed counters or LC devices used as a high-speed counter when using the FX3 compatible high-speed counter.

### Point

When (s) is a device supporting high-speed transfer

- When the DHCMOV instruction is executed, the latest value is acquired such as the current value of a high-speed counter and transferred to (d).

When (d) is a device supporting high-speed transfer

- When the DHCMOV instruction is executed, value such as the current value of a high-speed counter is changed.

## ■Effect of DHCMOV instruction

- By using both input interrupt and DHCMOV instruction, the current value of a high-speed counter can be received at the rising edge or falling edge of an external input.
- When DHCMOV instruction is used just before a comparison instruction (DCMP, DZCP or comparison contact instruction), the latest value of the high-speed counter is used in comparison.

## Precautions

- When it is necessary to execute comparison and outputting as soon as the current value of a high-speed counter changes, use the high-speed comparison table, multi-output high-speed comparison table, or one of the DHSCS, DHSCR, and DHSZ instructions.
- Do not overwrite the current value of a high-speed counter using the DHCMOV instruction while executing the pulse density (rotation speed measurement) or the DSPD instruction.
- Transfer is not possible between an SM supporting high-speed transfer and an SD supporting high-speed transfer.
- When the device supporting high-speed transfer is set as the transfer source (s) by the DHCMOV instruction while the high-speed I/O function is stopped, the previous value before stop is read out. However, if the function is not executed even once, the initial value is read out.

### Ex.

When SD5303, SD5302 (PWM pulse width) is set as the transfer source (s), the operation is executed as follows.

| Condition                                                      | Result                                                                              |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------|
| When the PWM function is not executed                          | "0" is read out. (This is not the value of the parameter that is set by GX Works3.) |
| When the PWM function was executed but it is currently stopped | The value when the PWM function was stopped is read out.                            |
| When the PWM function is executed                              | The latest value that is currently operating is read out.                           |

- When a high-speed counter SD device (current value, maximum value, minimum value) is read out individually, only the read SD device will be updated. Thus, there may be cases when the high-speed counter's SD device does not satisfy the relation of minimum value  $\leq$  current value  $\leq$  maximum value temporarily. Refer to the  MELSEC iQ-F FX5 User's Manual (Application) for details on the timing that the high-speed counter's SD device is updated.

### Point

The DHCMOV instruction is mainly used to read the current value of the high-speed counter/pulse width measurement and change the current address (in the user units) or the current address (in the pulse unit) of positioning.

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

This instruction sends or receives data by non-protocol communication via the built-in RS-485 port or the optional RS-232C or RS-485 serial ports installed in the CPU module. This instruction specifies the head device storing the sent data from the CPU module, the number of data bytes, the head device storing the received data, and the maximum number of bytes that can be received. For details, refer to MELSEC iQ-F FX5 User's Manual (Communication).

## Precautions

- It is not permitted to use other external device communication instructions on the same port.
- While this instruction is being driven, the communication format cannot be changed. Set this instruction to OFF before changing the communication format.
- When using the header and terminator, set them before driving this instruction. Do not change the values of the header and terminator while this instruction is being driven.

For other precautions, refer to MELSEC iQ-F FX5 User's Manual (Communication).

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                |

\*1 T, ST, and C cannot be used.

## Processing details

The operation status corresponding to the instruction code specified in (s2) of an inverter connected to the communication channel (n) whose station number is specified in (s1) is read and transferred to (d1). For details, refer to  MELSEC iQ-F FX5 User's Manual (Communication). (For the instruction codes, refer to the each inverter manual.)

## Precautions

Three devices are occupied from the device specified in (d2). Make sure that these devices are not used in other controls.

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

The control value specified in (s3) is written to the instruction code specified in (s2) of an inverter connected to the communication channel (n) whose station number is specified in (s1). For details, refer to  MELSEC iQ-F FX5 User's Manual (Communication). (For the instruction codes, refer to the each inverter manual.)

## Precautions

Three devices are occupied from the device specified in (d). Make sure that these devices are not used in other controls.

| (d2)    | ○                           | ○*1                       | —     | — | —           | —  | —                      | —        | — | —  | —      |

\*1 T, ST, and C cannot be used.

## Processing details

The value of the parameter (s2) is read from an inverter connected to the communication channel (n) whose station number is (s1), and output to (d1). For details, refer to  MELSEC iQ-F FX5 User's Manual (Communication). (For the parameter numbers, refer to the each inverter manual.)

## Precautions

Three devices are occupied from the device specified in (d2). Make sure that these devices are not used in other controls.

## Operation error
