

Programmable Controller

**MELSEC iQ-F**  
series

MELSEC iQ-F

FX5 Programming Manual

(Instructions, Standard Functions/Function Blocks)

---

# SAFETY PRECAUTIONS

---

(Read these precautions before use.)

Before using the MELSEC iQ-F series PLCs, please read the manual supplied with each product and the relevant manuals introduced in that manual carefully and pay full attention to safety to handle the product correctly.

Store this manual in a safe place so that it can be taken out and read whenever necessary. Always forward it to the end user.

## INTRODUCTION

---

This manual describes the instructions and functions/function blocks required for programming MELSEC iQ-F series systems. This manual and the related manuals should be read and the functions and performance of the MELSEC iQ-F series PLC should be understood before attempting to use the unit.

However, before using a program example introduced in this manual to the actual system, always confirm that it poses no problem for control of the target system.

### Regarding use of this product

---

- This product has been manufactured as a general-purpose part for general industries, and has not been designed or manufactured to be incorporated in a device or system used in purposes related to human life.
- Before using the product for special purposes such as nuclear power, electric power, aerospace, medicine or passenger movement vehicles, consult with Mitsubishi Electric.
- This product has been manufactured under strict quality control. However when installing the product where major accidents or losses could occur if the product fails, install appropriate backup or failsafe functions in the system.

### Note

---

- If in doubt at any stage during the installation of the product, always consult a professional electrical engineer who is qualified and trained in the local and national standards. If in doubt about the operation or use, please consult the nearest Mitsubishi Electric representative.
- Since the examples indicated by this manual, technical bulletin, catalog, etc. are used as a reference, please use it after confirming the function and safety of the equipment and system. Mitsubishi Electric will accept no responsibility for actual use of the product based on these illustrative examples.
- This manual content, specification etc. may be changed without a notice for improvement.
- The information in this manual has been carefully checked and is believed to be accurate; however, if you have noticed a doubtful point, an error, etc., please contact the nearest Mitsubishi Electric representative. When doing so, please provide the manual number given at the end of this manual.

| <b>CHAPTER 1 OVERVIEW</b> .....                                                                       | <b>22</b> |
| 1.1 Instruction Configuration .....                                                                   | 22        |
| 1.2 Data Specification Method .....                                                                   | 23        |
| Bit data .....                                                                                        | 26        |
| 16-bit data (word data) .....                                                                         | 27        |
| 32-bit data (double word data) .....                                                                  | 29        |
| Real number data (floating-point data) .....                                                          | 32        |
| Character string data .....                                                                           | 33        |
| 1.3 Execution Condition .....                                                                         | 35        |
| 1.4 Acceleration of Instruction Processing Time .....                                                 | 36        |
| <b>CHAPTER 2 PRECAUTIONS ON PROGRAMMING</b> .....                                                     | <b>39</b> |
| 2.1 Errors Common to Instructions .....                                                               | 39        |
| 2.2 Checking the Ranges of Instruction Runtime Devices and Labels .....                               | 39        |
| 2.3 Operations Arising when the OUT, SET/RST, and PLS/PLF Instructions of the Same Device are Used .. | 40        |
| 2.4 Handling general flags .....                                                                      | 45        |
| 2.5 Standard Function/Function Block Return Values .....                                              | 47        |

## PART 2 INSTRUCTION/FUNCTION LIST

|                                                     |           |
|-----------------------------------------------------|-----------|
| <b>CHAPTER 3 CPU MODULE INSTRUCTION</b> .....       | <b>50</b> |
| 3.1 Sequence Instruction .....                      | 50        |
| 3.2 Basic Instruction .....                         | 54        |
| 3.3 Application Instruction .....                   | 69        |
| 3.4 Step Ladder Instructions .....                  | 90        |
| 3.5 PID Control Instruction .....                   | 90        |
| 3.6 SFC Program Instructions .....                  | 91        |
| <b>CHAPTER 4 MODULE SPECIFIC INSTRUCTION</b> .....  | <b>93</b> |
| 4.1 Network Common Instruction .....                | 93        |
| 4.2 Ethernet Instruction .....                      | 93        |
| 4.3 CC-Link IE TSN Instructions .....               | 95        |
| 4.4 CC-Link IE Field Network Instruction .....      | 95        |
| 4.5 High-speed Counter Instruction .....            | 96        |
| 4.6 External Device Communication Instruction ..... | 97        |
| 4.7 Positioning Instruction .....                   | 98        |
| 4.8 BFM Device Read/ Write Instruction .....        | 99        |

## CHAPTER 5 STANDARD FUNCTIONS/FUNCTION BLOCKS 100

|            |                                            |            |
|------------|--------------------------------------------|------------|
| <b>5.1</b> | <b>Standard Functions</b>                  | <b>100</b> |
|            | Type conversion functions                  | 100        |
|            | Standard functions of one numeric variable | 105        |
|            | Standard arithmetic functions              | 106        |
|            | Standard bit shift functions               | 107        |
|            | Standard bitwise boolean functions         | 107        |
|            | Standard selection functions               | 108        |
|            | Standard comparison functions              | 108        |
|            | Standard character string functions        | 109        |
|            | Time data functions                        | 110        |
| <b>5.2</b> | <b>Standard Function Blocks</b>            | <b>111</b> |
|            | Bistable function blocks                   | 111        |
|            | Edge detection function blocks             | 111        |
|            | Counter function blocks                    | 111        |
|            | Timer function blocks                      | 112        |

## PART 3 CPU MODULE INSTRUCTIONS

### CHAPTER 6 SEQUENCE INSTRUCTIONS 114

|            |                                                                                       |            |
|------------|---------------------------------------------------------------------------------------|------------|
| <b>6.1</b> | <b>Contact Instructions</b>                                                           | <b>114</b> |
|            | Operation start, series connection, parallel connection                               | 114        |
|            | Pulse operation start, pulse series connection, pulse parallel connection             | 117        |
|            | Pulse NOT operation start, pulse NOT series connection, pulse NOT parallel connection | 121        |
| <b>6.2</b> | <b>Association Instruction</b>                                                        | <b>123</b> |
|            | Ladder block series/parallel connection                                               | 123        |
|            | Storing/reading/clearing the operation result                                         | 125        |
|            | Inverting the operation result                                                        | 128        |
|            | Converting the operation result into a pulse                                          | 129        |
| <b>6.3</b> | <b>Output Instructions</b>                                                            | <b>130</b> |
|            | Out (excluding the timer, counter and annunciator)                                    | 130        |
|            | Timer                                                                                 | 132        |
|            | Counter                                                                               | 135        |
|            | Long counter                                                                          | 137        |
|            | Annunciator                                                                           | 139        |
|            | Setting devices (excluding annunciator)                                               | 141        |
|            | Resetting devices (excluding annunciator)                                             | 143        |
|            | Setting annunciator                                                                   | 145        |
|            | Resetting annunciator                                                                 | 147        |
|            | Setting annunciator (with check time)                                                 | 149        |
|            | Resetting annunciator (smallest number reset)                                         | 151        |
|            | Rising edge output                                                                    | 152        |
|            | Falling edge output                                                                   | 154        |
|            | Inverting the bit device output                                                       | 156        |
|            | Inverting the bit device output                                                       | 157        |
| <b>6.4</b> | <b>Shift Instructions</b>                                                             | <b>159</b> |
|            | Shifting bit devices                                                                  | 159        |
|            | Shifting 16-bit data to the right by n bit(s)                                         | 161        |
|            | Shifting 16-bit data to the left by n bit(s)                                          | 163        |

|                                                   |                |
|---------------------------------------------------|----------------|
| Shifting n-bit data to the right by 1 bit         | 165            |
| Shifting n-bit data to the left by 1 bit          | 167            |
| Shifting n-word data to the right by 1 word       | 169            |
| Shifting n-word data to the left by 1 word        | 170            |
| Shifting n-bit(s) data to the right by (n) bit(s) | 171            |
| Shifting n-bit data to the left by n bit(s)       | 173            |
| Shifting n-word data to the right by n word(s)    | 175            |
| Shifting n-word data to the left by n word(s)     | 177            |
| <b>6.5 Master Control Instruction</b>             | <b>179</b>     |
| Setting/resetting the master control              | 179            |
| <b>6.6 Termination Instructions</b>               | <b>183</b>     |
| Ending the main routine program                   | 183            |
| Ending the sequence program                       | 186            |
| <b>6.7 Stop Instruction</b>                       | <b>188</b>     |
| Stopping the sequence program                     | 188            |
| <br><b>CHAPTER 7 BASIC INSTRUCTIONS</b>           | <br><b>189</b> |
| <b>7.1 Comparison Operation Instructions</b>      | <b>189</b>     |
| Comparing 16-bit binary data                      | 189            |
| Comparing 32-bit binary data                      | 192            |
| Comparison output 16-bit binary data              | 194            |
| Comparison output 32-bit binary data              | 196            |
| Comparing 16-bit binary data band                 | 198            |
| Comparing 32-bit binary data band                 | 200            |
| Comparing 16-bit binary block data                | 202            |
| Comparing 32-bit binary block data                | 205            |
| <b>7.2 Arithmetic Operation Instructions</b>      | <b>208</b>     |
| Adding 16-bit binary data                         | 208            |
| Subtracting 16-bit binary data                    | 214            |
| Adding 32-bit binary data                         | 220            |
| Subtracting 32-bit binary data                    | 226            |
| Multiplying 16-bit binary data                    | 232            |
| Dividing 16-bit binary data                       | 236            |
| Multiplying 32-bit binary data                    | 240            |
| Dividing 32-bit binary data                       | 244            |
| Adding BCD 4-digit data                           | 248            |
| Subtracting BCD 4-digit data                      | 250            |
| Adding BCD 8-digit data                           | 253            |
| Subtracting BCD 8-digit data                      | 256            |
| Multiplying BCD 4-digit data                      | 259            |

|             | Signed 32-bit bi-directional counters .....         | 774        |
| <b>8.16</b> | <b>Shortcut Control Instruction</b> .....           | <b>776</b> |
|             | Rotary table shortest direction control .....       | 776        |
| <b>8.17</b> | <b>Ramp Signal Instruction</b> .....                | <b>779</b> |
|             | Ramp signal .....                                   | 779        |
| <b>8.18</b> | <b>Pulse Related Instruction</b> .....              | <b>782</b> |
|             | Measuring the density of 16 bit binary pulses ..... | 782        |
|             | Measuring the density of 32 bit binary pulses ..... | 788        |
|             | 16 bit binary pulse output .....                    | 793        |
|             | 32 bit binary pulse output .....                    | 801        |
|             | 16 bit binary pulse width modulation .....          | 809        |
|             | 32 bit binary pulse width modulation .....          | 816        |
| <b>8.19</b> | <b>Input Matrix Instruction</b> .....               | <b>823</b> |
|             | Input matrix .....                                  | 823        |
| <b>8.20</b> | <b>Initial State</b> .....                          | <b>827</b> |
|             | Initial State .....                                 | 827        |
| <b>8.21</b> | <b>Drum Sequence</b> .....                          | <b>838</b> |
|             | 16-bit binary data absolute method .....            | 838        |
|             | 32-bit binary data absolute method .....            | 840        |
|             | Relative method .....                               | 842        |
| <b>8.22</b> | <b>Check Code</b> .....                             | <b>845</b> |
|             | Check code .....                                    | 845        |
| <b>8.23</b> | <b>Data Operation Instruction</b> .....             | <b>848</b> |
|             | Searching 16-bit data .....                         | 848        |
|             | Searching 32-bit data .....                         | 850        |
|             | Bit check of 16-bit data .....                      | 852        |
|             | Bit check of 32-bit data .....                      | 854        |
|             | Bit judgment of 16-bit data .....                   | 855        |
|             | Bit judgment of 32-bit data .....                   | 857        |
|             | Searching the maximum value of 16-bit data .....    | 859        |
|             | Searching the maximum value of 32-bit data .....    | 861        |
|             | Searching the minimum value of 16-bit data .....    | 863        |
|             | Searching the minimum value of 32-bit data .....    | 865        |
|             | Sorting 16-bit data .....                           | 867        |
|             | Sorting 16-bit data 2 .....                         | 870        |
|             | Sorting 32-bit data 2 .....                         | 873        |
|             | Adding 16-bit data .....                            | 876        |
|             | Adding 32-bit data .....                            | 878        |
|             | Calculating the mean value of 16-bit data .....     | 880        |
|             | Calculating the mean value of 32-bit data .....     | 882        |
|             | Calculating the square root of 16-bit data .....    | 884        |
|             | Calculating the square root of 32-bit data .....    | 886        |
|             | CRC calculation .....                               | 887        |
| <b>8.24</b> | <b>Indirect Address Read Instruction</b> .....      | <b>890</b> |
|             | Reading the indirect address .....                  | 890        |
| <b>8.25</b> | <b>Clock Instruction</b> .....                      | <b>892</b> |
|             | Reading clock data .....                            | 892        |

|                                                                               |                |
|-------------------------------------------------------------------------------|----------------|
| Writing clock data . . . . .                                                  | 894            |
| Adding clock data . . . . .                                                   | 897            |
| Subtracting clock data . . . . .                                              | 900            |
| Converting time data from hour/minute/second to seconds in 16 bits . . . . .  | 903            |
| Converting time data from hour/minute/second to seconds in 32 bits . . . . .  | 905            |
| Converting time data from seconds to hour/minute/second in 16 bits . . . . .  | 907            |
| Converting time data from seconds to hour/minute/second in 32 bits . . . . .  | 909            |
| Comparing date data . . . . .                                                 | 911            |
| Comparing time data . . . . .                                                 | 914            |
| Comparing clock data . . . . .                                                | 917            |
| Comparing clock data zones . . . . .                                          | 920            |
| <b>8.26 Timing Check Instruction . . . . .</b>                                | <b>923</b>     |
| Generating timing pulses . . . . .                                            | 923            |
| Hour meter . . . . .                                                          | 926            |

| Restarting a block . . . . .                                                  | 974            |
| Activating a step . . . . .                                                   | 976            |
| Deactivating a step . . . . .                                                 | 978            |
| Activating/deactivating a step . . . . .                                      | 980            |
| Batch-deactivating a step . . . . .                                           | 982            |
| <b>11.2 SFC Dedicated Instruction . . . . .</b>                               | <b>984</b>     |
| Creating a dummy transition condition . . . . .                               | 984            |

## PART 4 MODULE DEDICATED INSTRUCTION

### CHAPTER 12 NETWORK COMMON INSTRUCTION 986

|                                                                               |            |
|-------------------------------------------------------------------------------|------------|
| <b>12.1 Link Dedicated Instructions</b>                                       | <b>988</b> |
| Reading data from another station programmable controller                     | 988        |
| Reading data from another station programmable controller (with notification) | 994        |
| Writing data to another station programmable controller                       | 1000       |
| Writing data to another station programmable controller (with notification)   | 1008       |
| Sending data to another station programmable controller                       | 1016       |
| Receiving data from another station programmable controller                   | 1024       |

### CHAPTER 13 Ethernet INSTRUCTION 1030

|                                                              |             |
|--------------------------------------------------------------|-------------|
| <b>13.1 Built-in Ethernet Function Instruction</b>           | <b>1030</b> |
| Opening a connection                                         | 1030        |
| Closing a connection                                         | 1033        |
| <b>13.2 Socket Communications Function Instruction</b>       | <b>1035</b> |
| Reading receive data during the END processing               | 1035        |
| Sending data                                                 | 1038        |
| Reading connection information                               | 1041        |
| Reading socket communications receive data                   | 1043        |
| <b>13.3 Predefined Protocol Support Function Instruction</b> | <b>1045</b> |
| Executing the registered protocols                           | 1045        |
| <b>13.4 SLMP Frame Send Instruction</b>                      | <b>1049</b> |
| Sending the SLMP frame                                       | 1049        |
| <b>13.5 File Transfer Function Instruction</b>               | <b>1054</b> |
| Sending FTP client files                                     | 1054        |
| Retrieving FTP client files                                  | 1059        |
| <b>13.6 Ethernet Module</b>                                  | <b>1064</b> |
| Opening a connection                                         | 1064        |
| Closing a connection                                         | 1067        |
| Reading receive data                                         | 1069        |
| Sending data                                                 | 1071        |

### CHAPTER 14 CC-Link IE TSN INSTRUCTION 1073

|                                                   |             |
|---------------------------------------------------|-------------|
| <b>14.1 Own Station Number/IP Address Setting</b> | <b>1073</b> |
| <b>14.2 Sending an SLMP Frame</b>                 | <b>1076</b> |

### CHAPTER 15 CC-Link IE Field Network INSTRUCTION 1085

|                                                       |             |
|-------------------------------------------------------|-------------|
| <b>15.1 Setting parameters</b>                        | <b>1085</b> |
| <b>15.2 Setting the station number to own station</b> | <b>1088</b> |

### CHAPTER 16 HIGH-SPEED COUNTER INSTRUCTION 1091

|                                                       |             |
|-------------------------------------------------------|-------------|
| <b>16.1 High-speed Processing Instruction</b>         | <b>1091</b> |
| Setting 32-bit data comparison                        | 1091        |
| Reset 32-bit data comparison                          | 1094        |
| Comparison of 32-bit data band                        | 1097        |
| Start/stop of the 16-bit data high-speed I/O function | 1100        |
| Start/stop of the 32-bit data high-speed I/O function | 1104        |

|             |                                                            |             |
|-------------|------------------------------------------------------------|-------------|
| <b>16.2</b> | <b>High-speed Current Value Transfer Instruction</b> ..... | <b>1108</b> |
|             | High-speed current value transfer of 16-bit data .....     | 1108        |
|             | High-speed current value transfer of 32-bit data .....     | 1110        |

---

|                   |                                                  |             |
|-------------------|--------------------------------------------------|-------------|
| <b>CHAPTER 17</b> | <b>EXTERNAL DEVICE COMMUNICATION INSTRUCTION</b> | <b>1113</b> |
|-------------------|--------------------------------------------------|-------------|

---

|             |                                                               |             |

## **PART 5 STANDARD FUNCTIONS**

---

---

|                   |                                  |             |
|-------------------|----------------------------------|-------------|
| <b>CHAPTER 20</b> | <b>TYPE CONVERSION FUNCTIONS</b> | <b>1206</b> |
|-------------------|----------------------------------|-------------|

---

|             |                                       |             |
|-------------|---------------------------------------|-------------|
| <b>20.1</b> | <b>Converting BOOL to WORD</b> .....  | <b>1206</b> |
| <b>20.2</b> | <b>Converting BOOL to DWORD</b> ..... | <b>1208</b> |
| <b>20.3</b> | <b>Converting BOOL to INT</b> .....   | <b>1209</b> |

|       |                                         |      |
|-------|-----------------------------------------|------|
| 20.4  | Converting BOOL to DINT                 | 1210 |
| 20.5  | Converting BOOL to TIME                 | 1211 |
| 20.6  | Converting BOOL to STRING               | 1212 |
| 20.7  | Converting WORD to BOOL                 | 1213 |
| 20.8  | Converting WORD to DWORD                | 1214 |
| 20.9  | Converting WORD to INT                  | 1215 |
| 20.10 | Converting WORD to DINT                 | 1216 |
| 20.11 | Converting WORD to TIME                 | 1218 |
| 20.12 | Converting DWORD to BOOL                | 1219 |
| 20.13 | Converting DWORD to WORD                | 1220 |
| 20.14 | Converting DWORD to INT                 | 1222 |
| 20.15 | Converting DWORD to DINT                | 1224 |
| 20.16 | Converting DWORD to TIME                | 1225 |
| 20.17 | Converting INT to BOOL                  | 1226 |
| 20.18 | Converting INT to WORD                  | 1227 |
| 20.19 | Converting INT to DWORD                 | 1228 |
| 20.20 | Converting INT to DINT                  | 1230 |
| 20.21 | Converting INT to BCD                   | 1231 |
| 20.22 | Converting INT to REAL                  | 1233 |
| 20.23 | Converting INT to TIME                  | 1234 |
| 20.24 | Converting INT to STRING                | 1235 |
| 20.25 | Converting DINT to BOOL                 | 1237 |
| 20.26 | Converting DINT to WORD                 | 1238 |
| 20.27 | Converting DINT to DWORD                | 1240 |
| 20.28 | Converting DINT to INT                  | 1241 |
| 20.29 | Converting DINT to BCD                  | 1243 |
| 20.30 | Converting DINT to REAL                 | 1245 |
| 20.31 | Converting DINT to TIME                 | 1246 |
| 20.32 | Converting DINT to STRING               | 1247 |
| 20.33 | Converting BCD to INT                   | 1249 |
| 20.34 | Converting BCD to DINT                  | 1251 |
| 20.35 | Converting REAL to INT                  | 1253 |
| 20.36 | Converting REAL to DINT                 | 1255 |
| 20.37 | Converting REAL to STRING               | 1257 |
| 20.38 | Converting TIME to BOOL                 | 1260 |
| 20.39 | Converting TIME to WORD                 | 1261 |
| 20.40 | Converting TIME to DWORD                | 1262 |
| 20.41 | Converting TIME to INT                  | 1263 |
| 20.42 | Converting TIME to DINT                 | 1264 |
| 20.43 | Converting TIME to STRING               | 1265 |
| 20.44 | Converting STRING to BOOL               | 1267 |
| 20.45 | Converting STRING to INT                | 1268 |
| 20.46 | Converting STRING to DINT               | 1270 |
| 20.47 | Converting STRING to REAL               | 1272 |
| 20.48 | Converting STRING to TIME               | 1275 |
| 20.49 | Converting Bit Array to INT             | 1276 |
| 20.50 | Converting Bit Array to DINT            | 1277 |
| 20.51 | Converting INT to Bit Array             | 1278 |
| 20.52 | Converting DINT to Bit Array            | 1279 |
| 20.53 | Bit Array Copy                          | 1280 |
| 20.54 | Reading the Specified Bit of Word Label | 1281 |

|                                                      |                                                            |             |
|------------------------------------------------------|------------------------------------------------------------|-------------|
| 20.55                                                | Writing the Specified Bit of Word Label .....              | 1282        |
| 20.56                                                | Copying the Specified Bit of Word Label .....              | 1283        |
| 20.57                                                | Unnecessary of Type Conversion .....                       | 1284        |
| <b>CHAPTER 21 SINGLE NUMBER VARIABLE FUNCTIONS</b>   |                                                            | <b>1285</b> |
| 21.1                                                 | Absolute Value .....                                       | 1285        |
| 21.2                                                 | Square Root .....                                          | 1287        |
| 21.3                                                 | Natural Logarithm Operation .....                          | 1288        |
| 21.4                                                 | Calculating the Common Logarithm .....                     | 1289        |
| 21.5                                                 | Exponential Operation .....                                | 1291        |
| 21.6                                                 | Sine Operation .....                                       | 1292        |
| 21.7                                                 | Cosine Operation .....                                     | 1293        |
| 21.8                                                 | Tangent Operation .....                                    | 1294        |
| 21.9                                                 | Arc Sine Operation .....                                   | 1296        |
| 21.10                                                | Arc Cosine Operation .....                                 | 1298        |
| 21.11                                                | Arc Tangent Operation .....                                | 1300        |
| <b>CHAPTER 22 ARITHMETIC OPERATION FUNCTIONS</b>     |                                                            | <b>1302</b> |
| 22.1                                                 | Addition .....                                             | 1302        |
| 22.2                                                 | Multiplication .....                                       | 1304        |
| 22.3                                                 | Subtraction .....                                          | 1306        |
| 22.4                                                 | Division .....                                             | 1308        |
| 22.5                                                 | Remainder .....                                            | 1310        |
| 22.6                                                 | Exponentiation .....                                       | 1312        |
| 22.7                                                 | Move Operation .....                                       | 1314        |
| <b>CHAPTER 23 BIT SHIFT FUNCTIONS</b>                |                                                            | <b>1316</b> |
| 23.1                                                 | n-bit Left Shift .....                                     | 1316        |
| 23.2                                                 | n-bit Right Shift .....                                    | 1318        |
| 23.3                                                 | n-bit Left Rotation .....                                  | 1320        |
| 23.4                                                 | n-bit Right Rotation .....                                 | 1322        |
| <b>CHAPTER 24 STANDARD BITWISE BOOLEAN FUNCTIONS</b> |                                                            | <b>1324</b> |
| 24.1                                                 | AND Operation, OR Operation, XOR Operation .....           | 1324        |
| 24.2                                                 | Logical Negation .....                                     | 1326        |
| <b>CHAPTER 25 SELECTION FUNCTIONS</b>                |                                                            | <b>1327</b> |

| 28.4 | Division .....       | 1362 |

## **PART 6 FUNCTION BLOCKS**

### **CHAPTER 29 BISTABLE FUNCTION BLOCKS 1366**

|      |                                                 |      |
|------|-------------------------------------------------|------|
| 29.1 | Bistable Function Blocks (Set Priority) .....   | 1366 |
| 29.2 | Bistable Function Blocks (Reset Priority) ..... | 1368 |

### **CHAPTER 30 EDGE DETECTION FUNCTION BLOCKS 1370**

|      |                             |      |
|------|-----------------------------|------|
| 30.1 | Rising Edge Detector .....  | 1370 |
| 30.2 | Falling Edge Detector ..... | 1372 |

### **CHAPTER 31 COUNTER FUNCTION BLOCKS 1374**

|      |                              |      |
|------|------------------------------|------|
| 31.1 | Up Counter .....             | 1374 |
| 31.2 | Down Counter .....           | 1376 |
| 31.3 | Up-down Counter .....        | 1378 |
| 31.4 | Counter Function Block ..... | 1381 |

### **CHAPTER 32 TIMER FUNCTION BLOCKS 1383**

|      |                             |      |
|------|-----------------------------|------|
| 32.1 | Pulse Timer .....           | 1383 |
| 32.2 | On-delay Timer .....        | 1385 |
| 32.3 | Off-delay Timer .....       | 1387 |
| 32.4 | Timer Function Blocks ..... | 1389 |

## **APPENDIX 1392**

|                   |                                                            |             |
|-------------------|------------------------------------------------------------|-------------|
| <b>Appendix 1</b> | <b>Instruction Processing Time .....</b>                   | <b>1392</b> |
|                   | Instruction processing time (High-speed instruction) ..... | 1392        |
|                   | Instruction processing time .....                          | 1397        |
| <b>Appendix 2</b> | <b>Number of Instruction Steps .....</b>                   | <b>1433</b> |
| <b>Appendix 3</b> | <b>Added and Changed Functions .....</b>                   | <b>1454</b> |

## **INSTRUCTION INDEX 1457**

| Battery                              | Different name for FX3U-32BL                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Bus conversion module                | Generic term for Bus conversion module (extension cable type) and Bus conversion module (extension connector type)                                                                                                                                                                                                                                                                                                                                                   |
| Extension power supply module        | Generic term for FX5 extension power supply module and FX3 extension power supply module                                                                                                                                                                                                                                                                                                                                                                             |
| FX3                                  | Generic term for FX3S, FX3G, FX3GC, FX3U, and FX3UC PLCs                                                                                                                                                                                                                                                                                                                                                                                                             |
| FX3 intelligent function module      | Generic term for FX3U-4AD, FX3U-4DA, FX3U-4LC, FX3U-1PG, FX3U-2HC, FX3U-16CCL-M, FX3U-64CCL, FX3U-128ASL-M, and FX3U-32DP                                                                                                                                                                                                                                                                                                                                            |
| FX5                                  | Generic term for FX5S, FX5UJ, FX5U, and FX5UC PLCs                                                                                                                                                                                                                                                                                                                                                                                                                   |
| FX5 CPU module                       | Generic term for FX5S CPU module, FX5UJ CPU module, FX5U CPU module, and FX5UC CPU module                                                                                                                                                                                                                                                                                                                                                                            |
| FX5S CPU module                      | Generic term for FX5S-30MR/ES, FX5S-30MT/ES, FX5S-30MT/ESS, FX5S-40MR/ES, FX5S-40MT/ES, FX5S-40MT/ESS, FX5S-60MR/ES, FX5S-60MT/ES, FX5S-60MT/ESS, FX5S-80MR/ES <sup>*1</sup> , FX5S-80MT/ES <sup>*1</sup> , FX5S-80MT/ESS <sup>*1</sup> , FX5S-30MR/DS, FX5S-30MT/DS, FX5S-30MT/DSS, FX5S-40MR/DS, FX5S-40MT/DS, FX5S-40MT/DSS, FX5S-60MR/DS, FX5S-60MT/DS, FX5S-60MT/DSS, FX5S-80MR/DS <sup>*1</sup> , FX5S-80MT/DS <sup>*1</sup> , and FX5S-80MT/DSS <sup>*1</sup> |
| FX5U CPU module                      | Generic term for FX5U-32MR/ES, FX5U-32MT/ES, FX5U-32MT/ESS, FX5U-64MR/ES, FX5U-64MT/ES, FX5U-64MT/ESS, FX5U-80MR/ES, FX5U-80MT/ES, FX5U-80MT/ESS, FX5U-32MR/DS, FX5U-32MT/DS, FX5U-32MT/DSS, FX5U-64MR/DS, FX5U-64MT/DS, FX5U-64MT/DSS, FX5U-80MR/DS, FX5U-80MT/DS, and FX5U-80MT/DSS                                                                                                                                                                                |
| FX5UC CPU module                     | Generic term for FX5UC-32MT/D, FX5UC-32MT/DSS, FX5UC-64MT/D, FX5UC-64MT/DSS, FX5UC-96MT/D, FX5UC-96MT/DSS, FX5UC-32MT/DS-TS, FX5UC-32MT/DSS-TS, and FX5UC-32MR/DS-TS                                                                                                                                                                                                                                                                                                 |
| FX5UJ CPU module                     | Generic term for FX5UJ-24MR/ES, FX5UJ-24MT/ES, FX5UJ-24MT/ESS, FX5UJ-40MR/ES, FX5UJ-40MT/ES, FX5UJ-40MT/ESS, FX5UJ-60MR/ES, FX5UJ-60MT/ES, FX5UJ-60MT/ESS, FX5UJ-24MR/DS, FX5UJ-24MT/DS, FX5UJ-24MT/DSS, FX5UJ-40MR/DS, FX5UJ-40MT/DS, FX5UJ-40MT/DSS, FX5UJ-60MR/DS, FX5UJ-60MT/DS, and FX5UJ-60MT/DSS                                                                                                                                                              |
| GX Works3                            | The product name of the software package, SWnDND-GXW3, for the MELSEC programmable controllers (The 'n' represents a version.)                                                                                                                                                                                                                                                                                                                                       |
| High-speed pulse input/output module | Generic term for FX5-16ET/ES-H and FX5-16ET/ESS-H                                                                                                                                                                                                                                                                                                                                                                                                                    |
| I/O module                           | Generic term for Input modules, Output modules, Input/output modules, Powered input/output modules, and High-speed pulse input/output modules                                                                                                                                                                                                                                                                                                                        |
| Input module                         | Generic term for Input modules (extension cable type) and Input modules (extension connector type)                                                                                                                                                                                                                                                                                                                                                                   |
| Intelligent function module          | Generic term for FX5 intelligent function modules and FX3 intelligent function modules                                                                                                                                                                                                                                                                                                                                                                               |
| Intelligent module                   | The abbreviation for intelligent function modules                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Output module                        | Generic term for Output modules (extension cable type) and Output modules (extension connector type)                                                                                                                                                                                                                                                                                                                                                                 |
| Peripheral device                    | Generic term for engineering tools and GOTs                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SD memory card                       | Generic term for NZ1MEM-2GBSD, NZ1MEM-4GBSD, NZ1MEM-8GBSD, NZ1MEM-16GBSD, L1MEM-2GBSD and L1MEM-4GBSD SD memory cards.<br>Abbreviation of Secure Digital Memory Card. Device that stores data using flash memory.                                                                                                                                                                                                                                                    |

### Special function timer

#### STMR

FX5S FX5UJ FX5U FX5UC

This instruction uses the four devices from the device specified by (d) to perform four types of timer output.

Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                    | Range      | Data type            | Data type (label)                       |
|---------|------------------------------------------------|------------|----------------------|-----------------------------------------|
| (s1)    | Used timer number (operates as a 100 ms timer) | —          | Device name          | ANY16                                   |
| (s2)    | Timer set value                                | 1 to 32767 | 16-bit signed binary | ANY16                                   |
| (d)     | Start bit number to be output                  | —          | Bit                  | ANYBIT_ARRAY<br>(Number of elements: 4) |
| EN      | Execution condition                            | —          | Bit                  | BOOL                                    |
| ENO     | Execution result                               | —          | Bit                  | BOOL                                    |

#### ■Applicable devices

| Operand | Bit | Word           | Double word |    | Indirect specification | Constant |   |   | Others |
|---------|-----|----------------|-------------|----|------------------------|----------|---|---|--------|
|         |     |                | LC          | LZ |                        | K        | H | E |        |
| (s1)    | —   | —              | —           | —  | ○                      | —        | — | — | —      |
| (s2)    | ○   | ○              | ○           | ○  | ○                      | ○        | — | — | —      |
| (d)     | ○   | ○ <sup>2</sup> | —           | —  | —                      | —        | — | — | —      |

<sup>1</sup> Only T can be used.  
<sup>2</sup> T, ST, C cannot be used.

#### ■Control data

| Operand: (d) |                                                                                                                                                                             | Setting range | Set by |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| Device       | Description                                                                                                                                                                 |               |        |
| +0           | Off delay timer output:<br>Turns on at the rising edge of the command of the STMR instruction and turns off when the time specified by (s2) elapses after the falling edge. | —             | System |
| +1           | One-shot timer output after turning off:<br>Turns on at the falling edge of the command of the STMR instruction and turns off when the time specified by (s2) elapses.      | —             | System |
| (d)+2        | One-shot timer output after turning on:<br>Turns on at the rising edge of the command of the STMR instruction and turns off when the time specified by (s2) elapses.        | —             | System |
| (d)+3        | One-shot timer output after turning on:<br>Turns on at the rising edge of the command of the STMR instruction and turns off when the time specified by (s2) elapses.        | —             | System |

#### Processing details

• This instruction uses the four devices from the device specified by (d) to perform four types of timer output.

#### Precautions

- The timer number specified in this instruction cannot be used in other general circuits (such as OUT instruction). If the timer number is used in other general circuits, the timer malfunctions.
- The timer specified by (s1) starts counting as a 100 ms timer on the rising edge of the command contact.
- Four devices are occupied from a device specified in (d). Make sure that such devices are not used in other controls for the machine.
- If the command contact is turned off, (d), (d)+1, and (d)+3 turn off when the set time elapses. (d)+2 and the timer (s1) are immediately reset.

#### Operation error

| Error code (SD0/SD067) | Description                                                               |
|------------------------|---------------------------------------------------------------------------|
| 2820H                  | The device range specified by (d) exceeds the corresponding device range. |
| 3405H                  | The value specified by (s2) is outside the following range.<br>1 to 32767 |

① Indicates the instruction symbol.

- The instruction symbol with brackets means multiple instructions. For example, "GRY(P)(U)" means the GRY, GRYP, GRY\_U, and GRYP\_U instructions.

| Instruction symbol            | Description of symbol                                          |
|-------------------------------|----------------------------------------------------------------|
| Instruction symbol with "(P)" | The instruction is executed on the rising edge.                |
| Instruction symbol with "(U)" | The instruction handles 16-bit or 32-bit unsigned binary data. |

- The instruction symbol with "□" means multiple instructions. For example, "LDDT□" means the LDDT=, LDDT<>, LDDT>, LDDT<=, LDDT<, and LDDT>= instructions.

② Indicates the availability of instructions for each CPU module. (The instruction cannot be used with CPU modules marked with an ×.)

③ Indicates the description format of the ladder diagram, FBD/LD language and ST (structured text) language  
Instruction symbols are input in each corresponding place surrounded in a square in the ladder diagram.

④ Indicates the description, setting range, data type, and data type (label) of each operand.

- For the data type, refer to the following.

📖 MELSEC iQ-F FX5 Programming Manual (Program Design)

⑤ Indicates the applicable devices for each operand. The following table describes the usage classification.

| Operand                          | Bit                                                                                                                                                               | Word                                                                                                                                             |                     |   | Double word      |    | Indirect specification | Constant |   |    | Others <sup>*5</sup>           |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|---|------------------|----|------------------------|----------|---|----|--------------------------------|

\*1 For the description of each device, refer to the following.

📖 MELSEC iQ-F FX5 User's Manual (Application)

\*2 "○" is described in positions where bit devices or digit specification of bit devices is available.

\*3 When T, ST, C, and LC are used with an instruction other than the following instructions, they can be used only as word data. They cannot be used as bit data.

[Instruction which can be used as bit data]

LD, LDI, AND, ANI, OR, ORI, LDP, LDF, ANDP, ANDF, ORP, ORF, LDPI, LDFI, ANDPI, ANDFI, ORPI, ORFI, OUT, RST, BKRST, MOVB(P), CMLB(P)

\*4 "○" is described in positions where word device or bit specification of word device is available.

\*5 Devices which can be set are described in the "Others" column.

⑥ Depending on the instruction, the control data to set the operation of the instruction exists. When the "Set by" column is "User", the value must be specified according to the setting range.

⑦ Indicates the function details of the instruction. When no details are described, the following programs correspond to "Interrupt program".

- Interrupt program using the interrupt pointer (I)
- Fixed scan execution type program
- Event execution type program which is triggered by an interrupt by the interrupt pointer (I)

⑧ Indicates the cautions.

⑨ Indicates an error code (hexadecimal) which occurs at the execution and the error description when the instruction has a specific operation error.

- A device in which an error code is stored is described in the error code column. When an error code is stored in SD0/SD8067, the error flag (SM0, SM1, SM56, SM8067) turns on.

How to read PART 5 and PART 6

The contents described in this section are provided only for explaining how to read this manual. Thus, the actual description may differ.

Setting data

■Descriptions, types, and data types

| Argument            | Description                                        | Type            | Data type |
|---------------------|----------------------------------------------------|-----------------|-----------|
| EN                  | Execution condition (TRUE: Execution, FALSE: Stop) | Input variable  | BOOL      |
| s(IN)               | Input                                              | Input variable  | DINT      |
| ENO                 | Output status (TRUE: Normal, FALSE: Abnormal)      | Output variable | BOOL      |
| d(DINT_TO_BOOL(_E)) | Output                                             | Output variable | BOOL      |

Processing details

■Operation processing

- These functions convert the DINT type data input to (s) to BOOL type data and output from (d).
- When the input value is 0, these functions output "FALSE".
- When the input value is any value other than 0, these functions output "TRUE".

(s)

0

12345678

DINT

(d)

FALSE

TRUE

BOOL

- A value input to (s) is the DINT type data value.

■Operation result

1. Function without EN/ENO

The operation processing is executed. The operation output value is output from (d).

2. Function with EN/ENO

The following table lists the execution conditions and operation results.

| Execution condition       | Operation result    |                        |
|---------------------------|---------------------|------------------------|
| EN                        | ENO                 | (d)                    |
| TRUE (Executes operation) | TRUE                | Operation output value |
| FALSE (Stops operation)   | FALSE <sup>*1</sup> | Indefinite value       |

<sup>\*1</sup> When FALSE is output from ENO, data output from (d) is undefined. In that case, modify a program so that the data output from (d) is not used.

Operation error

There is no operation error.

20 TYPE CONVERSION FUNCTIONS  
20.25 Converting DINT to BOOL 1201

1Indicates function symbols.

When character strings in brackets are added to the end of the function symbol for standard functions and function blocks, the function symbol indicates multiple functions. For example, "DINT\_TO\_INT(\_E)" means "DINT\_TO\_INT" and "DINT\_TO\_INT\_E".

| Function symbol                           | Description of symbol                                                                                      |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Function symbol to which "(_E)" is added. | Indicates that the description format with EN/ENO can be used in the standard function and function block. |

2Indicates the availability of standard functions or function blocks for each CPU module. (The standard function or function block cannot be used with CPU modules marked with an ×.)

3Indicates the description format of the ladder diagram, FBD/LD language and ST (structured text) language.

In the square , either of the following symbol should be described.

- Standard function: Function symbol
- Standard function block: Instance name and function block symbol

The sign of return value of the standard function of FBD/LD is not displayed.

4Indicates the description, type and data type of each argument.

5Indicates the functions of each standard function or function block.

⑥ Indicates an error code which occurs at the execution and the error description when the standard function or the function block has a specific operation error.

A device in which an error code is stored is described in the error code column. When an error code is stored in SD0, the error flag SM0 turns on.

# PART 1 OVERVIEW

Part 1 consists of the following chapter.

1 OVERVIEW

---

2 PRECAUTIONS ON PROGRAMMING

---

# 1 OVERVIEW

## 1.1 Instruction Configuration

Many instructions available for CPU module are each divided into the instruction part and device part.

The instruction part and device part are used as follows.

- Instruction part: Indicates the function of the relevant instruction.
- Device part: Indicates the data used for the instruction.

The device part is further classified to source data, destination data, and numerical data.

### Source (s)

Source is the data used in the operation.

Depending on the label or device specified in each instruction, the source becomes as follows.

| Type                      | Description                                                                                                                                                                                                                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Constant                  | The constant specifies a numerical value used in the operation.<br>It is set during program creation and cannot be changed during program execution.                                                                                                                                                                        |
| Bit device<br>Word device | The user specifies the device where the data to be used in the operation is stored.<br>Necessary data must be thus stored in the specified device before operation execution.<br>By changing the data to be stored in the specified device during program execution, the data to be used by the instruction can be changed. |

### Destination (d)

Data after operation is stored in the destination area.

However, some instructions require the data to be used in the operation to be stored before the operation.

**Ex.**

Binary 16-bit data addition instruction

(1): The data required for operation is stored before the operation.

(2): Only the operation result is stored.

A label or device to store data must be set for the destination.

### Numerical values (n)

In an instruction which uses multiple devices or an instruction which specifies the number of repetitions, data to be processed, and character strings, use numerical values to specify the number of devices, transfers, data, and character strings.

**Ex.**

Block transfer instruction

(1): The number of transfers executed by the BMOV instruction is specified.

A numerical value from 0 to 65535 or 0 to 4294967295 can be set for the size such as the number of devices, transfers, or characters.\*1

Note, however, that when the size specification such as the number of devices, transfers, or characters is 0, the relevant instruction results in non-processing.

\*1 The setting range varies depending on the instruction. For details, refer to the description of each instruction.

## 1.2 Data Specification Method

The following table lists the types of data that can be used for instructions in CPU modules.

| Data                                   | Classification                                           |
|----------------------------------------|----------------------------------------------------------|
| Bit data                               | Bit data                                                 |
| 16-bit data (word data)                | 16-bit signed binary data<br>16-bit unsigned binary data |
| 32-bit data (double-word data)         | 32-bit signed binary data<br>32-bit unsigned binary data |
| Real number data (floating-point data) | Single-precision real number data                        |
| BCD data                               | BCD 4-digit data<br>BCD 8-digit data                     |
| String data                            | String<br>Unicode character string                       |

### Device data

| Data type                    | Description                                                                                                                                              | Specifiable device/constant <sup>*1</sup>                                                                                                                                                                                       |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit                          | Bit data can be handled.<br>☞ Page 26 Bit data                                                                                                           | <ul style="list-style-type: none"> <li>• Bit device</li> <li>• Bit specification of word device</li> </ul>                                                                                                                      |
| Word                         | Word data can be handled.<br>☞ Page 27 16-bit data (word data)                                                                                           | <ul style="list-style-type: none"> <li>• Word device</li> <li>• Digit specification of bit devices (K1 to K4)<sup>*2</sup></li> </ul>                                                                                           |
| 16-bit signed binary         | 16-bit data can be handled.                                                                                                                              | <ul style="list-style-type: none"> <li>• Decimal constant</li> <li>• Hexadecimal constant</li> </ul>                                                                                                                            |
| 16-bit unsigned binary       | The value range varies depending on whether the value is signed or unsigned.<br>☞ Page 27 16-bit data (word data)                                        |                                                                                                                                                                                                                                 |
| Double word                  | Double-word data can be handled.<br>☞ Page 29 32-bit data (double word data)                                                                             | <ul style="list-style-type: none"> <li>• Word device</li> <li>• Double-word device</li> </ul>                                                                                                                                   |
| 32-bit signed binary         | Two consecutive sets of 32-bit data or 16-bit data can be handled.                                                                                       | <ul style="list-style-type: none"> <li>• Digit specification of bit devices (K1 to K8)<sup>*2</sup></li> <li>• Decimal constant</li> <li>• Hexadecimal constant</li> </ul>                                                      |
| 32-bit unsigned binary       | The value range varies depending on whether the value is signed or unsigned.<br>☞ Page 29 32-bit data (double word data)                                 |                                                                                                                                                                                                                                 |

| ANY16_ARRAY             | Word [signed], word [unsigned]/bit string [16 bits]                                                                                                                         |
| ANY16_S_ARRAY           | Word [signed]                                                                                                                                                               |
| ANY16_U_ARRAY           | Word [unsigned]/bit string [16 bits]                                                                                                                                        |
| ANY32_ARRAY             | Double word [signed], double word [unsigned]/bit string [32 bits]                                                                                                           |
| ANY32_S_ARRAY           | Double word [signed]                                                                                                                                                        |
| ANY32_U_ARRAY           | Double word [unsigned]/bit string [32 bits]                                                                                                                                 |
| ANY_REAL_ARRAY          | Single-precision real number                                                                                                                                                |
| ANY_REAL_32_ARRAY       | Single-precision real number                                                                                                                                                |
| ANY_STRING_ARRAY        | Character string                                                                                                                                                            |
| ANY_STRING_SINGLE_ARRAY | Character string                                                                                                                                                            |
| ANY_STRING_DOUBLE_ARRAY | Character string [Unicode]                                                                                                                                                  |
| STRUCT_ARRAY            | Structures                                                                                                                                                                  |

# Bit data

## Data size and data range

Bit data is handled in increments of bits such as contacts and coils.

| Data name | Data size | Value range |
|-----------|-----------|-------------|
| Bit data  | 1 bit     | 0, 1        |

## Handling bit data with bit devices and labels

Bit data of one point per point can be handled.

## Handling bit data with bit word devices

By specifying a bit number for a word device, bit data of the specified bit number can be handled.

A bit in a word device can be specified by "Word device number.Bit number".

A bit number can be specified in hexadecimal in the range from 0 to F.

For example, bit 5 (b5) of D0 is specified as D0.5, and bit 10 (b10) of D0 is specified as D0.A.

The following word devices support bit specification.

| Item                                         | Device                                                                                                                                                                                                                                 |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Word devices which support bit specification | <ul style="list-style-type: none"><li>• Data register (D)</li><li>• Link register (W)</li><li>• Link special register (SW)</li><li>• Special register (SD)</li><li>• Module access device (U□\G)</li><li>• File register (R)</li></ul> |

## Handling bit data with word type labels

By specifying a bit number for a word [unsigned]/bit string [16 bits] type label or word [signed] type label, bit data of the specified bit number can be handled.

A bit in a word type label can be specified by "Label name.Bit number".

## 16-bit data (word data)

### Data size and data range

16-bit data includes signed and unsigned 16-bit data.

In signed 16-bit data, a negative number is represented in two's complement.

| Data name            | Data size        | Value range      |                      |
|----------------------|------------------|------------------|----------------------|
|                      |                  | Decimal notation | Hexadecimal notation |
| Signed 16-bit data   | 16 bits (1 word) | -32768 to 32767  | 0000H to FFFFH       |
| Unsigned 16-bit data |                  | 0 to 65535       |                      |

### Handling 16-bit data with bit devices

A bit device can be handled as 16-bit data by performing digit specification.

| Item       | Notation                                                             | Example |
|------------|----------------------------------------------------------------------|---------|
| Bit device | K□ Bit device start number                                           | K4X10   |
|            | □: Number of digits (Specify the number within the range of 1 to 4.) | K2M113  |

### Handling 16-bit data with bit type array labels

A bit type array label can be handled as 16-bit data by performing digit specification.

The following table shows the notation for handling a bit type array label as 16-bit data by digit specification.

| Item                 | Notation                                                                                                               | Example  |
|----------------------|------------------------------------------------------------------------------------------------------------------------|----------|
| Bit type array label | K□ Label name                                                                                                          | K1L_BOOL |
|                      | □: Number of digits (Specify the number within the range of 1 to 4.)<br>Specify a label name without an array element. |          |

## Digit specification range

The following table lists the range of 16-bit data for each digit specification.

| Digit specification | Decimal notation                                                        | Hexadecimal notation |
|---------------------|-------------------------------------------------------------------------|----------------------|
| K1                  | 0 to 15                                                                 | 0H to FH             |
| K2                  | 0 to 255                                                                | 00H to FFH           |
| K3                  | 0 to 4095                                                               | 000H to FFFH         |
| K4                  | Signed 16-bit data: -32768 to 32767<br>Unsigned 16-bit data: 0 to 65535 | 0000H to FFFFH       |

### Ex.

When digit specification is made for X0, the applicable number of points is as follows.

- K1X0→4 points from X0 to X3
- K2X0→8 points from X0 to X7
- K3X0→12 points from X0 to X13
- K4X0→16 points from X0 to X17

## Specifying a bit device with digit specification in the source (s)

When a bit device with digit specification is specified in the source of an instruction, 0 is stored in the bits, which follow the bit for which digit specification is made in the source, in the word device of the destination.

| Ladder example                                                              | Processing |
|-----------------------------------------------------------------------------|------------|
| <ul style="list-style-type: none"> <li>• 16-bit data instruction</li> </ul> |            |

## Specifying a bit device with digit specification in the destination (d)

When a digit specification is made in the destination of an instruction, the number of points by the digit specification is applicable in the destination.

The bit devices after the number of points specified by nibble remain unchanged.

| Ladder example                                                                            | Processing                            |
|-------------------------------------------------------------------------------------------|---------------------------------------|
| <ul style="list-style-type: none"> <li>• When the source data is a word device</li> </ul> | <p>(1): The data remain the same.</p> |

## Handling 16-bit data with word devices/labels

### ■Word device

One point of word device can handle 16-bit data.

### ■Word type label

One point of word type label can handle 16-bit data.

## 32-bit data (double word data)

### Data size and data range

32-bit data includes signed and unsigned 32-bit data.

In signed 32-bit data, a negative number is represented in two's complement.

| Data name            | Data size        | Value range               |                        |
|----------------------|------------------|---------------------------|------------------------|
|                      |                  | Decimal notation          | Hexadecimal notation   |
| Signed 32-bit data   | 32 bits (2 word) | -2147483648 to 2147483647 | 00000000H to FFFFFFFFH |
| Unsigned 32-bit data |                  | 0 to 4294967295           |                        |

### Handling 32-bit data with bit devices

A bit device can be handled as 32-bit data by performing digit specification.

| Item       | Notation                                                                                            | Example         |
|------------|-----------------------------------------------------------------------------------------------------|-----------------|
| Bit device | K□Bit device start number<br>□: Number of digits (Specify the number within the range from 1 to 8.) | K8X10<br>K6B018 |

### Handling 32-bit data with bit type array labels

A bit type array label can be handled as 32-bit data by performing digit specification.

The following table shows the notation for handling a bit type array label as 32-bit data by digit specification.

| Item                 | Notation                                                                                                                             | Example  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------|----------|
| Bit type array label | K□Label name<br>□: Number of digits (Specify a number within the range of 1 to 8.)<br>Specify a label name without an array element. | K8L_BOOL |

## Digit specification range

The following table lists the range of 32-bit data for each digit specification.

| Digit specification | Decimal notation                                                                       | Hexadecimal notation   |
|---------------------|----------------------------------------------------------------------------------------|------------------------|
| K1                  | 0 to 15                                                                                | 0H to FH               |
| K2                  | 0 to 255                                                                               | 00H to FFH             |
| K3                  | 0 to 4095                                                                              | 000H to FFFH           |
| K4                  | 0 to 65535                                                                             | 0000H to FFFFH         |
| K5                  | 0 to 1048575                                                                           | 00000H to FFFFFH       |
| K6                  | 0 to 16777215                                                                          | 000000H to FFFFFFFH    |
| K7                  | 0 to 268435455                                                                         | 0000000H to FFFFFFFFH  |
| K8                  | Signed 32-bit data: -2147483648 to 2147483647<br>Unsigned 32-bit data: 0 to 4294967295 | 00000000H to FFFFFFFFH |

### Ex.

When digit specification is made for X0, the applicable number of points is as follows.

- K1X0→4 points from X0 to X3
- K2X0→8 points from X0 to X7
- K3X0→12 points from X0 to X13
- K4X0→16 points from X0 to X17
- K5X0→20 points from X0 to X23
- K6X0→24 points from X0 to X27
- K7X0→28 points from X0 to X33
- K8X0→32 points from X0 to X37

## ■Specifying a bit device with digit specification in the source (s)

When a bit device with digit specification is specified in the source of an instruction, 0 is stored in the bits, which follow the bit for which digit specification is made in the source, in the word device of the destination.

| Ladder example                                                                                                                                              | Processing                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>32-bit data instruction</li> </ul>  |  |

## ■Specifying a bit device with digit specification in the destination (d)

When a digit specification is made in the destination of an instruction, the number of points by the digit specification is applicable in the destination.

The bit devices after the number of points specified by nibble remain unchanged.

| Ladder example                                                                                                                                                             | Processing                                                                                                                |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>When the source data is a word device</li> </ul>  |  <p>(1): The data remain the same.</p> |

## Handling 32-bit data with word devices/labels

### ■Word device

Two points of word device can handle 32-bit data.

Note, however, that one point of the following devices can handle 32-bit data.

- Long counter (LC)
- Long index register (LZ)

### ■Double word type label

One point of double word device can handle 32-bit data.

# Real number data (floating-point data)

## Data size and data range

Real number data includes single-precision 32-bit real number data.

Real number data can be stored only in devices other than bit devices or in single-precision real data type labels.

| Data name                                                                |                 | Data size        | Value range                                    |
|--------------------------------------------------------------------------|-----------------|------------------|------------------------------------------------|
| Single-precision real number data (single-precision floating-point data) | Positive number | 32 bits (2 word) | $2^{-126} \leq \text{real number} < 2^{128}$   |
|                                                                          | Zero            |                  | 0                                              |
|                                                                          | Negative number |                  | $-2^{128} < \text{real number} \leq -2^{-126}$ |

## Configuration of single-precision real number data

Single-precision real number data consists of a sign, mantissa, and exponent, and is expressed as shown below.

$$\boxed{\text{Sign}} \quad 1. \quad \boxed{\text{Mantissa}} \times 2^{\boxed{\text{Exponent}}}$$

The following figure shows the bit configuration of the internal expression of single-precision real number data and the meaning of each part.

### ■Sign (1 bit)

This bit represents the positive or negative sign of a numerical value. "0" indicates a positive number or 0. "1" Indicates a negative number.

### ■Mantissa (23 bits)

A mantissa means XXXXX... of  $1.XXXXX \times 2^N$  representing a single-precision real number in binary.

### ■Exponent (8 bits)

An exponent means N of  $1.XXXXX \times 2^N$  representing a single-precision real number in binary. The following table shows the relationships between the exponent value and N of a single-precision real number.

| Exponent (b23 to b30) | FFH      | FEH | FDH | ... | 81H | 80H | 7FH | 7EH | ... | 02H  | 01H  | 00H      |
|-----------------------|----------|-----|-----|-----|-----|-----|-----|-----|-----|------|------|----------|
| N                     | Not used | 127 | 126 | ... | 2   | 1   | 0   | -1  | ... | -125 | -126 | Not used |

## Precautions

### ■When setting an input value of single-precision real number from the engineering tool

The number of significant digits is about 7 because the engineering tool processes single precision real number data in 32-bit single precision.

When the input value of single-precision real number data exceeds 7 digits, the 8th digit is rounded off.

Therefore, if the rounded-off value goes out of the range from -2147483648 to 2147483647, it will not be an intended value.

**Ex.**

When "2147483647" is set as an input value, it is handled as "2147484000" because 8th digit "6" is rounded off.

**Ex.**

When "E1.1754943562" is set as an input value, it is handled as "E1.175494" because 8th digit "3" is rounded off.

The monitor function of the engineering tool can monitor real number data of CPU modules.

To represent "0" in real number data, set all numbers in each of the following range to 0.

- Single-precision real number data: b0 to b31

The setting range of real number data is as follows.

- Single precision real number data:  $-2^{128} < \text{single precision real number data} \leq -2^{126}$ ,  $0, 2^{-126} \leq [\text{single precision real number data}] < 2^{128}$

Do not specify "-0" (only the most significant bit is 1) in real number data. Performing a real number operation using -0 results in an operation error.

## Character string data

### Format of character string data

The following table lists the types of character string data, each of which ends with a NULL code to be handled as a character string.

| Type                     | Character code                   | Last character |
|--------------------------|----------------------------------|----------------|
| Character string         | ASCII code                       | NULL(00H)      |
| Unicode character string | Unicode (UTF-16 (little endian)) | NULL(0000H)    |

Character string data is stored in devices or an array in ascending order of device numbers or array element numbers.

### Method for expressing a character string

When a character string or a Unicode character string is specified in a program, an error may occur depending on the expressing method.

The expressing methods in the programming languages are shown below.

#### ■Ladder program

| Data type                  | Expressing method                                                                |
|----------------------------|----------------------------------------------------------------------------------|
| String                     | Enclose character strings with single (') or double quotation marks (").         |
| Character string [Unicode] | Enclose Unicode character strings with single (') or double quotation marks ("). |

#### ■ST program

| Data type                  | Expressing method                                                  |
|----------------------------|--------------------------------------------------------------------|
| String                     | Enclose character strings with single quotation marks (').         |
| Character string [Unicode] | Enclose Unicode character strings with double quotation marks ("). |

#### ■FBD/LD program

| Data type                  | Expressing method                                                  |
|----------------------------|--------------------------------------------------------------------|
| String                     | Enclose character strings with single quotation marks (').         |
| Character string [Unicode] | Enclose Unicode character strings with double quotation marks ("). |

## Data range

The following table summarizes the ranges of character string data.

| Type                                   | Maximum number of character strings                            | Maximum number of character strings that can be handled in the program |
|----------------------------------------|----------------------------------------------------------------|------------------------------------------------------------------------|
| Character string                       | 255 single-byte characters (excluding the last NULL character) | 16383 characters (excluding the last NULL character)                   |
| Unicode character string <sup>*1</sup> | 255 characters (NULL at the end is not included.)              |                                                                        |

<sup>\*1</sup> For Unicode strings, characters in the basic multilingual plane can be used.

## Number of words required for storing data

Character string data can be stored in word devices.

The following table lists the numbers of words required for storing character string data.

| Number of character string bytes | Number of words required for storing character strings | Number of words needed for storing Unicode character string |
|----------------------------------|--------------------------------------------------------|-------------------------------------------------------------|
| 0 byte                           | 1 [word]                                               | 1 [word]                                                    |
| Odd number of bytes              | (Number of character string bytes+1) ÷ 2 [words]       | — (Because one character is in an even byte.)               |
| Even number of bytes             | (Number of character string bytes÷2) +1 [words]        | Number of characters + 1 [words]                            |

## Character string data storage location

An image of the character string data storage location is shown below.

### ■Character strings

In each character string storage image, "NULL" indicates a NULL code (00H).

| Character string to be stored | Image of storing character string data from D0                                                                                                                                            | Image of storing character string data from word type label array arrayA[0] |   |      |                                                                        |      |   |                                                                                                                                         |   |      |                                                                                                                                                                                                                |      |   |   |   |   |   |      |   |      |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|---|------|------------------------------------------------------------------------|------|---|-----------------------------------------------------------------------------------------------------------------------------------------|---|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---|---|---|---|---|------|---|------|
| ' ' (null character string)   | D0 <table><tr><td>NULL</td><td>:</td><td>NULL</td></tr></table>                                                                                                                           | NULL                                                                        | : | NULL | arrayA[0] <table><tr><td>NULL</td><td>:</td><td>NULL</td></tr></table> | NULL | : | NULL                                                                                                                                    |   |      |                                                                                                                                                                                                                |      |   |   |   |   |   |      |   |      |
| NULL                          | :                                                                                                                                                                                         | NULL                                                                        |   |      |                                                                        |      |   |                                                                                                                                         |   |      |                                                                                                                                                                                                                |      |   |   |   |   |   |      |   |      |
| NULL                          | :                                                                                                                                                                                         | NULL                                                                        |   |      |                                                                        |      |   |                                                                                                                                         |   |      |                                                                                                                                                                                                                |      |   |   |   |   |   |      |   |      |

### ■Unicode character strings

In each Unicode character string storage image, "NULL" indicates the NULL code (0000H).

| Character string to be stored | Image of storing character string data from D0                                                                                                                           | Image of storing character string data from word type label array arrayA[0] |                                                 |      |   |    |   |    |   |    |      |                                                                                                                                                                                                             |           |   |           |   |           |   |           |   |           |      |

# 1.3 Execution Condition

## Types of execution conditions

The following are the five types of execution conditions of the instructions and functions of CPU module.

| Execution condition |                                                                                   | Description                                                                                                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| On                  |  | An instruction is executed during on. It is executed only while the precondition of the instruction is on. When the precondition is off, the instruction is not executed.                                               |
| Rising edge         |  | An instruction is executed one time when turned on. It is executed only once on the rising edge (off to on) of the precondition of the instruction and is no longer executed later even when the condition turns on.    |
| Off                 |  | An instruction is executed during off. It is executed only while the precondition of the instruction is off. When the precondition is on, the instruction is not executed.                                              |
| Falling edge        |  | An instruction is executed one time when turned off. It is executed only once on the falling edge (on to off) of the precondition of the instruction and is no longer executed later even when the condition turns off. |
| Always              | —                                                                                 | An instruction is always executed regardless of whether the precondition of the instruction is on or off. When the precondition is off, the instruction performs off processing.                                        |

## Execution condition of each instruction

The execution condition varies depending on the instruction. The following table lists the execution conditions of individual instructions.

| Execution condition | Applicable instruction                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| On                  | All instructions except for the following                                                                                                                                                                                                                                                                                                                                                                                                                          |

# 1.4 Acceleration of Instruction Processing Time

## High-speed instruction

In some instructions, when the device and label specified in each operand satisfy the specific condition, the instruction processing time is accelerated.

Such accelerated instructions are called high-speed instructions.

## The instructions capable of accelerating and the conditions of acceleration

The table below shows the instructions capable of accelerating and the conditions of acceleration (conditions of non-acceleration).

| Classification                   | Instruction symbol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Conditions of non-acceleration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

\*<sup>1</sup> When specifying the nibble of a label, some instructions are accelerated depending on the assignment position of the label. However, because the assignment position of label cannot be checked and changed, check the actual operation.

## Execution time of high-speed instruction

For execution time of high-speed instruction, refer to the following.

 Page 1392 Instruction Processing Time

# 2 PRECAUTIONS ON PROGRAMMING

## 2.1 Errors Common to Instructions

The following table lists the conditions under which an error occurs when the instruction is executed.

| Error content <sup>*1</sup>                                                                                                                                                                                        | Error code (SD0/SD8067) |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| An I/O number which corresponds to no module is specified.                                                                                                                                                         | 2801H                   |
| <ul style="list-style-type: none"><li>An I/O number which is out of range (0 to 1777 (Octal number)) is specified.</li><li>The device or label specified by the instruction exceeds the available range.</li></ul> | 2820H                   |
| The range of the buffer memory of the module specified by the instruction is exceeded.                                                                                                                             | 2823H                   |

<sup>\*1</sup> For a contact instruction, an error is not detected but the operation result becomes no continuity.

## 2.2 Checking the Ranges of Instruction Runtime Devices and Labels

### Checking the ranges of devices and labels

When a device or label is specified in an instruction, range check is performed. If a range exceeding that of the relevant device or label is specified, an error occurs.

The same applies when a label assigned to a device is specified in an instruction in the program.

Create such a program that the operation result falls within the range of the relevant device or label.

**Ex.**

When a global device is specified

## 2.3 Operations Arising when the OUT, SET/RST, and PLS/PLF Instructions of the Same Device are Used

If two or more OUT, SET/RST, and PLS/PLF instructions are executed using the same device during one scan, they operate as described in this section.

### For OUT instructions of the same device

More than one OUT instruction of the same device must not be issued during one scan.

Otherwise, the specified device turns on or off, depending on the operation result up to each OUT instruction while it is in execution.

In this case, the device may turn on/off during one scan because the on/off state of the specified device is determined during execution of each OUT instruction.

The following figure shows the behavior arising when a circuit turning on/off the same internal relay (M0) is created with input X0 and X1.

- (1) Since X0 is on, M0 turns on.
- (2) Since X1 is off, M0 turns off.
- (3) Since X0 is off, M0 remains off.
- (4) Since X1 is on, M0 turns on.

If output (Y) is specified using an OUT instruction, the on/off state of the last OUT instruction executed during the one scan will be output.

## If SET/RST instructions of the same device are used

### ■For SET instructions

The SET instruction turns on the specified device if the execution command is on, and causes no operation if it is off.

Thus, if two or more SET instructions of the same device are executed during one scan, the specified device turns on even if one execution command is on.

### ■For RST instructions

The RST instruction turns off the specified device if the execution command is on, and causes no operation if it is off.

Thus, if two or more RST instructions of the same device are executed during one scan, the specified device turns off even if one execution command is off.

### ■If the SET and RST instructions of the same device exist in one scan

If the SET and RST instructions of the same device exist in one scan, the SET instruction turns on the specified device if the execution command is on, and turns off the specified device if it is on.

If both the SET and RST instructions are off, the on/off state of the specified device will be unchanged.

(1) Since X0 is on, M0 turns on.

(2) Since X1 is off, M0 remains on. (The RST instruction results in non-processing.)

(3) Since X0 is on, M0 remains on. (The SET instruction results in non-processing.)

(4) Since X1 is on, M0 turns off.

If output (Y) is specified using a SET/RST instruction, the on/off state of the last SET/RST instruction executed during the one scan will be output.

## If PLS instructions of the same device are used

The PLS instruction turns on the specified device when the execution command specifies an off-to-on change. The specified device is turned off unless the execution command specifies an off-to-on change (i.e. off to off, on to on, on to off).

Thus, if two or more PLS instructions of the same device are issued during one scan, the specified device is turned on when the execution command of each PLS instruction specifies an off-to-on change. The specified device is turned off unless the execution command specifies an off-to-on change.

Thus, if two or more PLS instructions are issued during one scan, the device turned on by a PLS instruction may not turn on for one scan.

- If X0 and X1 differs in the on/off timing (i.e. the specified device does not turn on for one scan)

- (1) Since X0 turns on, M0 turns on.
- (2) Since X1 is other than turning on, M0 turns off.
- (3) Since X0 is other than turning on, M0 remains off.
- (4) Since X1 turns on, M0 turns on.

- If the off-to-on changes of X0 and X1 are at the same timing

- (1) Since X0 turns on, M0 turns on.  
 (2) Since X1 turns on, M0 remains on.  
 (3) Since X0 is other than turning on, M0 turns off.  
 (4) Since X1 is other than turning on, M0 remains off.

If output (Y) is specified using a PLS instruction, the on/off state of the last PLS instruction executed during the one scan will be output.

## If PLF instructions of the same device are used

The PLF instruction turns on the specified device when the execution command specifies an on-to-off change. The specified device is turned off unless the execution command specifies an on-to-off change (i.e. off to off, off to on, on to on).

Thus, if two or more PLF instructions of the same device are issued during one scan, the specified device is turned on when the execution command of each PLF instruction specifies an on-to-off change. The specified device is turned off unless the execution command specifies an on-to-off change.

Thus, if two or more PLF instructions are issued during one scan, the device turned on by a PLF instruction may not turn on for one scan.

- If X0 and X1 differs in the on/off timing (i.e. the specified device does not turn on for one scan)

- (1) Since X0 turns off, M0 turns on.
- (2) Since X1 is other than turning off, M0 turns off.
- (3) Since X0 is other than turning off, M0 remains off.
- (4) Since X1 is other than turning off, M0 remains off.

- If the on-to-off changes of X0 and X1 are at the same timing

- (1) Since X0 turns off, M0 turns on.  
 (2) Since X1 turns off, M0 remains on.  
 (3) Since X0 is other than turning off, M0 turns off.  
 (4) Since X1 is other than turning off, M0 remains off.

If output (Y) is specified using a PLF instruction, the on/off state of the last PLF instruction executed during the one scan will be output.

## 2.4 Handling general flags

In some types of instructions, the following flags operate:

- SM8020: Zero flag
- SM8021: Borrow flag
- SM8022: Carry flag
- SM8029: Instruction execution complete flag
- SM8090: Block comparison signal
- SM8304: Zero flag (MUL, DIV instructions only)
- SM8306: Carry flag (MUL, DIV instructions only)
- SM8328: Instruction non-execution flag
- SM8329: Instruction execution abnormal end flag

These general flags turn ON or OFF every time instructions turn ON, but do not change when various instructions turn OFF or when errors occur.

Because multiple instructions change the status of these flags, the ON/OFF status of flags change every time such instructions are executed.

Program general flag contacts directly under each instruction. (☞ Page 46 Program containing many flags (example of SM8029 (Instruction execution complete flag)))

## Program containing many flags (example of SM8029 (Instruction execution complete flag))

When two or more SM8029 (Instruction execution complete flag) are programmed together for instructions which operate the same flag, it is difficult to determine which instruction executes which flag. Also, the flag corresponding to each instruction cannot be read normally.

For using flags in any positions other than directly under instructions, refer to  Page 47 Method for using flags in any positions other than directly under instructions (example of SM8029 (Instruction execution complete flag)).

## Method for using flags in any positions other than directly under instructions (example of SM8029 (Instruction execution complete flag))

When two or more instructions are programmed, general flags turn ON or OFF when each instruction turns ON.

Accordingly, when using a flag in any position other than directly under an instruction, set another device to ON or OFF just under the instruction, and then use the contact of the device as the command input.

## 2.5 Standard Function/Function Block Return Values

When standard functions/function blocks are used, always set a device or label for the output variable, and make sure to receive the return value.

If the output variable is not set, an error may occur after writing to the PLC.

# 3 CPU MODULE INSTRUCTION

## 3.1 Sequence Instruction

### Contact instruction

#### ■Operation start, series connection, parallel connection

| Instruction symbol | Description                                                        | Reference |
|--------------------|--------------------------------------------------------------------|-----------|
| LD                 | Starts logical operation (Starts NO contact logical operation)     | Page 114  |
| LDI                | Starts logical NOT operation (Starts NC contact logical operation) |           |
| AND                | Logical AND (NO contact series connection)                         |           |
| ANI                | Logical NAND (NC contact series connection)                        |           |
| OR                 | Logical OR (NO contact parallel connection)                        |           |
| ORI                | Logical NOR (NC contact parallel connection)                       |           |

#### ■Pulse operation start, pulse series connection, pulse parallel connection

| Instruction symbol | Description                            | Reference |
|--------------------|----------------------------------------|-----------|
| LDP                | Starts rising edge pulse operation     | Page 117  |
| LDF                | Starts falling edge pulse operation    |           |
| ANDP               | Rising edge pulse series connection    |           |
| ANDF               | Falling edge pulse series connection   |           |
| ORP                | Rising edge pulse parallel connection  |           |
| ORF                | Falling edge pulse parallel connection |           |

#### ■Pulse NOT operation start, pulse NOT series connection, pulse NOT parallel connection

| Instruction symbol | Description                                | Reference |
|--------------------|--------------------------------------------|-----------|
| LDPI               | Starts rising edge pulse NOT operation     | Page 121  |
| LDFI               | Starts falling edge pulse NOT operation    |           |
| ANDPI              | Rising edge pulse NOT series connection    |           |
| ANDFI              | Falling edge pulse NOT series connection   |           |
| ORPI               | Rising edge pulse NOT parallel connection  |           |
| ORFI               | Falling edge pulse NOT parallel connection |           |

### Association instruction

#### ■Ladder block series/parallel connection

| Instruction symbol | Description                                                            | Reference |
|--------------------|------------------------------------------------------------------------|-----------|
| ANB                | AND between logical blocks (series connection between logical blocks)  | Page 123  |
| ORB                | OR between logical blocks (parallel connection between logical blocks) |           |

#### ■Storing/reading/clearing the operation result

| Instruction symbol | Description                                            | Reference |
|--------------------|--------------------------------------------------------|-----------|
| MPS                | Stores the operation result                            | Page 125  |
| MRD                | Reads the operation result stored by MPS               |           |
| MPP                | Reads and resets of the operation result stored by MPS |           |

#### ■Inverting the operation result

| Instruction symbol | Description                       | Reference |
|--------------------|-----------------------------------|-----------|
| INV                | Inversion of the operation result | Page 128  |

## ■Converting the operation result into a pulse

| Instruction symbol | Description                                          | Reference |
|--------------------|------------------------------------------------------|-----------|
| MEP                | Conversion of operation result to rising edge pulse  | Page 129  |
| MEF                | Conversion of operation result to falling edge pulse |           |

## Output instruction

### ■Out (excluding the timer, counter and annunciator)

| Instruction symbol | Description   | Reference |
|--------------------|---------------|-----------|
| OUT                | Device output | Page 130  |

### ■Timer (low-speed, high-speed, low-speed retentive, high-speed retentive)

| Instruction symbol | Description                | Reference |
|--------------------|----------------------------|-----------|
| OUT T              | Low-speed timer            | Page 132  |
| OUTH T             | Timer                      |           |
| OUTHS T            | High-speed timer           |           |
| OUT ST             | Low-speed retentive timer  |           |
| OUTH ST            | Retentive timer            |           |
| OUTHS ST           | High-speed retentive timer |           |

### ■Counter, long counter

| Instruction symbol | Description  | Reference |
|--------------------|--------------|-----------|
| OUT C              | Counter      | Page 135  |
| OUT LC             | Long counter | Page 137  |

### ■Annunciator

| Instruction symbol | Description | Reference |
|--------------------|-------------|-----------|
| OUT F              | Annunciator | Page 139  |

### ■Setting devices (excluding annunciator)

| Instruction symbol | Description  | Reference |
|--------------------|--------------|-----------|
| SET                | Sets devices | Page 141  |

### ■Resetting devices (excluding annunciator)

| Instruction symbol | Description    | Reference |
|--------------------|----------------|-----------|
| RST                | Resets devices | Page 143  |

### ■Setting/resetting annunciator

| Instruction symbol | Description                                | Reference |
|--------------------|--------------------------------------------|-----------|
| SET F              | Sets annunciator                           | Page 145  |
| RST F              | Resets annunciator                         | Page 147  |
| ANS                | Sets annunciator (with evaluation time)    | Page 149  |
| ANR                | Resets annunciator (smallest number reset) | Page 151  |
| ANRP               |                                            |           |

### ■Rising/falling edge output

| Instruction symbol | Description                                                                         | Reference |
|--------------------|-------------------------------------------------------------------------------------|-----------|
| PLS                | Generates a pulse for 1 cycle of a program at the rising edge of the input signal.  | Page 152  |
| PLF                | Generates a pulse for 1 cycle of a program at the falling edge of the input signal. | Page 154  |

### ■Inverting the bit device output

| Instruction symbol | Description                | Reference |
|--------------------|----------------------------|-----------|
| FF                 | Inversion of device output | Page 156  |
| ALT                |                            | Page 157  |
| ALTP               |                            |           |

## Shift instruction

### ■Shifting bit devices

| Instruction symbol | Description               | Reference |
|--------------------|---------------------------|-----------|
| SFT                | 1 bit shift of the device | Page 159  |
| SFTP               |                           |           |

### ■Shifting 16-bit data to the right/left by n bit (s)

| Instruction symbol | Description                                                                       | Reference |
|--------------------|-----------------------------------------------------------------------------------|-----------|
| SFR                |  | Page 161  |
| SFRP               |                                                                                   |           |
| SFL                |  | Page 163  |
| SFLP               |                                                                                   |           |

### ■Shifting n-bit data to the right/left by 1 bit

| Instruction symbol | Description                                                                         | Reference |
|--------------------|-------------------------------------------------------------------------------------|-----------|
| BSFR               |   | Page 165  |
| BSFRP              |                                                                                     |           |
| BSFL               |  | Page 167  |
| BSFLP              |                                                                                     |           |

### ■Shifting n-word data to the right/left by 1 word

| Instruction symbol | Description                                                                         | Reference |
|--------------------|-------------------------------------------------------------------------------------|-----------|
| DSFR               |  | Page 169  |
| DSFRP              |                                                                                     |           |
| DSFL               |  | Page 170  |
| DSFLP              |                                                                                     |           |

## ■Shifting n-bit data to the right/left by n bit (s)

| Instruction symbol | Description | Reference |
|--------------------|-------------|-----------|
| SFTR               |             | Page 171  |
| SFTRP              |             |           |
| SFTL               |             |           |
| SFTLP              |             |           |

## ■Shifting n-word data to the right/left by n word (s)

| Instruction symbol | Description | Reference |
|--------------------|-------------|-----------|
| WSFR               |             | Page 175  |
| WSFRP              |             |           |
| WSFL               |             |           |
| WSFLP              |             |           |

## Master control instruction

### ■Setting/resetting the master control

| Instruction symbol | Description             | Reference |
|--------------------|-------------------------|-----------|
| MC                 | Starts master control   | Page 179  |
| MCR                | Releases master control |           |

## Termination instruction

### ■Ending the main routine program

| Instruction symbol | Description                   | Reference |
|--------------------|-------------------------------|-----------|
| FEND               | Ends the main routine program | Page 183  |

### ■Ending the sequence program

| Instruction symbol | Description               | Reference |
|--------------------|---------------------------|-----------|
| END                | Ends the sequence program | Page 186  |

## Stop instruction

### ■Stopping the sequence program

| Instruction symbol | Description                                                                                                                                         | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| STOP               | Stops the sequence operation after input conditions are met.<br>Executes the sequence program, upon setting the RUN/STOP/RESET switch to RUN again. | Page 188  |

## 3.2 Basic Instruction

### Comparison operation instruction

#### ■Comparing 16-bit binary data

| Instruction symbol         | Description               | Reference |
|----------------------------|---------------------------|-----------|
| LD=, AND=, OR=             | (s1)=(s2): Conductive     | Page 189  |
| LD= _U, AND= _U, OR= _U    | (s1)≠(s2): Non-Conductive |           |
| LD<>, AND<>, OR<>          | (s1)≠(s2): Conductive     |           |
| LD<> _U, AND<> _U, OR<> _U | (s1)=(s2): Non-Conductive |           |
| LD>, AND>, OR>             | (s1)>(s2): Conductive     |           |
| LD> _U, AND> _U, OR> _U    | (s1)≤(s2): Non-Conductive |           |
| LD≤, AND≤, OR≤             | (s1)≤(s2): Conductive     |           |
| LD≤ _U, AND≤ _U, OR≤ _U    | (s1)>(s2): Non-Conductive |           |
| LD<, AND<, OR<             | (s1)<(s2): Conductive     |           |
| LD< _U, AND< _U, OR< _U    | (s1)≥(s2): Non-Conductive |           |
| LD≥, AND≥, OR≥             | (s1)≥(s2): Conductive     |           |
| LD≥ _U, AND≥ _U, OR≥ _U    | (s1)<(s2): Non-Conductive |           |

#### ■Comparing 32-bit binary data

| Instruction symbol            | Description                                     | Reference |
|-------------------------------|-------------------------------------------------|-----------|
| LDD=, ANDD=, ORD=             | [(s1)+1, (s1)] = [(s2)+1, (s2)]: Conductive     | Page 192  |
| LDD= _U, ANDD= _U, ORD= _U    | [(s1)+1, (s1)] ≠ [(s2)+1, (s2)]: Non-Conductive |           |
| LDD<>, ANDD<>, ORD<>          | [(s1)+1, (s1)] ≠ [(s2)+1, (s2)]: Conductive     |           |
| LDD<> _U, ANDD<> _U, ORD<> _U | [(s1)+1, (s1)] = [(s2)+1, (s2)]: Non-Conductive |           |
| LDD>, ANDD>, ORD>             | [(s1)+1, (s1)] > [(s2)+1, (s2)]: Conductive     |           |
| LDD> _U, ANDD> _U, ORD> _U    | [(s1)+1, (s1)] ≤ [(s2)+1, (s2)]: Non-Conductive |           |
| LDD≤, ANDD≤, ORD≤             | [(s1)+1, (s1)] ≤ [(s2)+1, (s2)]: Conductive     |           |
| LDD≤ _U, ANDD≤ _U, ORD≤ _U    | [(s1)+1, (s1)] > [(s2)+1, (s2)]: Non-Conductive |           |
| LDD<, ANDD<, ORD<             | [(s1)+1, (s1)] < [(s2)+1, (s2)]: Conductive     |           |
| LDD< _U, ANDD< _U, ORD< _U    | [(s1)+1, (s1)] ≥ [(s2)+1, (s2)]: Non-Conductive |           |
| LDD≥, ANDD≥, ORD≥             | [(s1)+1, (s1)] ≥ [(s2)+1, (s2)]: Conductive     |           |
| LDD≥ _U, ANDD≥ _U, ORD≥ _U    | [(s1)+1, (s1)] < [(s2)+1, (s2)]: Non-Conductive |           |

#### ■Comparison output 16-bit binary data

| Instruction symbol | Description              | Reference |
|--------------------|--------------------------|-----------|
| CMP                | (s1)>(s2): (d) is on     | Page 194  |
| CMPP               | (s1)=(s2): (d) + 1 is on |           |
| CMP _U             | (s1)<(s2): (d) + 2 is on |           |
| CMPP _U            |                          |           |

#### ■Comparison output 32-bit binary data

| Instruction symbol | Description                                    | Reference |
|--------------------|------------------------------------------------|-----------|

| ZRSTP              |                                                                                                                                                                                                                             |           |

## Data conversion instruction

### ■Converting binary data to BCD 4-digit/8-digit data

| Instruction symbol | Description                                                                       | Reference |
|--------------------|-----------------------------------------------------------------------------------|-----------|
| BCD                | Converts the specified 16-bit binary data (0 to 9999) to BCD 4-digit data.        | Page 318  |
| BCDP               |  |           |
| DBCD               | Converts the specified 32-bit binary data (0 to 99999999) to BCD 8-digit data.    | Page 320  |
| DBCDP              |  |           |

### ■Converting BCD 4-digit/8-digit data to binary data

| Instruction symbol | Description                                                                         | Reference |
|--------------------|-------------------------------------------------------------------------------------|-----------|
| BIN                | Converts the specified BCD 4-digit data (0 to 9999) to 16-bit binary data.          | Page 322  |
| BINP               |  |           |
| DBIN               | Converts the specified BCD 8-digit data (0 to 99999999) to 32-bit binary data.      | Page 324  |
| DBINP              |  |           |

### ■Converting single-precision real number to 16-bit/32-bit signed binary data

| Instruction symbol | Description                                                                                                   | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------|-----------|
| FLT2INT            | Converts the specified single-precision real number (-32768 to 32767) to 16-bit signed binary data.           | Page 326  |
| FLT2INTP           |  <p>(1): Real number</p>   |           |
| FLT2DINT           | Converts the specified single-precision real number (-2147483648 to 2147483647) to 32-bit signed binary data. | Page 330  |
| FLT2DINTP          |  <p>(1): Real number</p>   |           |

### ■Converting single-precision real number to 16-bit/32-bit unsigned binary data

| Instruction symbol | Description                                                                                                 | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------|-----------|
| FLT2UINT           | Converts the specified single-precision real number (0 to 65535) to 16-bit unsigned binary data.            | Page 328  |
| FLT2UINTP          |  <p>(1): Real number</p> |           |
| FLT2UDINT          | Converts the specified single-precision real number (0 to 4294967295) to 32-bit unsigned binary data.       | Page 332  |
| FLT2UDINTP         |  <p>(1): Real number</p> |           |

### ■Converting 16-bit signed binary data to 16-bit/32-bit unsigned binary data

| Instruction symbol | Description                                                                                                                                       | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| INT2UINT           | Converts 16-bit signed data in the device specified by (s) to 16-bit unsigned data, and stores the converted data in the device specified by (d). | Page 334  |
| INT2UINTP          |                                                                                                                                                   |           |
| INT2UDINT          | Converts 16-bit signed data in the device specified by (s) to 32-bit unsigned data, and stores the converted data in the device specified by (d). | Page 336  |
| INT2UDINTP         |                                                                                                                                                   |           |

### ■Converting 16-bit signed binary data to 32-bit signed binary data

| Instruction symbol | Description                                                                                                                                     | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| INT2DINT           | Converts 16-bit signed data in the device specified by (s) to 32-bit signed data, and stores the converted data in the device specified by (d). | Page 335  |
| INT2DINTP          |                                                                                                                                                 |           |

### ■Converting 16-bit unsigned binary data to 16-bit/32-bit signed binary data

| Instruction symbol | Description                                                                                                                                       | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| UINT2INT           | Converts 16-bit unsigned data in the device specified by (s) to 16-bit signed data, and stores the converted data in the device specified by (d). | Page 337  |
| UINT2INTP          |                                                                                                                                                   |           |
| UINT2DINT          | Converts 16-bit unsigned data in the device specified by (s) to 32-bit signed data, and stores the converted data in the device specified by (d). | Page 338  |

| ENCO               |  | Page 375  |
| ENCOP              |                                                                                     |           |

## ■Seven-segment decoding

| Instruction symbol | Description                                                                                                                   | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|-----------|
| SEGD               | Decoded to data for the seven-segment display unit in the device specified by (s), and stores in the device specified by (d). | Page 377  |
| SEGDP              |                                                                                                                               |           |

## ■Seven-segment with latch

| Instruction symbol | Description                                                                                                                                                                      | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| SEGL               | The 4-digit numeric value stored in (s) is converted into BCD data, and each digit is output to the seven-segment display unit with the BCD decoder by the time division method. | Page 379  |

## ■Separating 4 bits from 16-bit data

| Instruction symbol | Description                                                                                                                | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|-----------|
| DIS                | Separates the 16-bit data specified by (s) into 4-bit units and stores in the lower 4 bits of (n) points from (d). (n < 4) | Page 382  |
| DISP               |                                                                                                                            |           |

## ■Connecting 4 bits to 16-bit data

| Instruction symbol | Description                                                                                                                             | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|-----------|
| UNI                | Connects the lower 4 bits of (n) points from the device specified by (s), and stores the result in the device specified by (d). (n < 4) | Page 384  |
| UNIP               |                                                                                                                                         |           |

### ■Separating/connecting the specified number of bits

| Instruction symbol | Description                                                                                                                                                                                    | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| NDIS               | Separates the data in the devices starting from the one specified by (s1) into bits specified by the devices from (s2), and stores them to the devices starting from the one specified by (d). | Page 386  |
| NDISP              |                                                                                                                                                                                                |           |
| NUNI               | Connects the data in the devices starting from the one specified by (s1) with bits specified by the devices from (s2), and stores them to the devices starting from the one specified by (d).  | Page 388  |
| NUNIP              |                                                                                                                                                                                                |           |

### ■Separating/connecting data in byte units

| Instruction symbol | Description                                                                                                                                                                  | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| WTOB               | Breaks (n) points of 16 bit data from the device specified by (s) into 8-bit units, and stores in the devices starting from the one specified by (d).                        | Page 390  |
| WTOBP              |                                                                                                                                                                              |           |
| BTOW               | Connects the lower 8 bits of 16-bit data of (n) points from the device specified by (s) into 16-bit units, and stores in the devices starting from the one specified by (d). | Page 392  |
| BTOWP              |                                                                                                                                                                              |           |

## Digital Switch

| Instruction symbol | Description                                                                    | Reference |
|--------------------|--------------------------------------------------------------------------------|-----------|
| DSW                | Stores the value of the (n) sets of digital switches connected to (s) to (d2). | Page 395  |

## Data transfer instruction

### ■Transferring 16-bit/32-bit data

| Instruction symbol | Description                         | Reference |
|--------------------|-------------------------------------|-----------|
| MOV                | (s) $\longrightarrow$ (d)           | Page 397  |
| MOVP               |                                     |           |
| DMOV               | (s+1, s) $\longrightarrow$ (d+1, d) | Page 399  |
| DMOVP              |                                     |           |

### ■Inverting and transferring 16-bit/32-bit data

| Instruction symbol | Description                                      | Reference |
|--------------------|--------------------------------------------------|-----------|
| CML                | $\overline{(s)}$ $\longrightarrow$ (d)           | Page 401  |
| CMLP               |                                                  |           |
| DCML               | $\overline{(s+1, s)}$ $\longrightarrow$ (d+1, d) | Page 403  |
| DCMLP              |                                                  |           |

### ■Shift move

| Instruction symbol | Description                                                                                 | Reference |
|--------------------|---------------------------------------------------------------------------------------------|-----------|
| SMOV               | Shifts the specified no. of digits from the word device specified by (s), and store in (d). | Page 404  |
| SMOVP              |                                                                                             |           |

### ■Inverting and transferring 1-bit data

| Instruction symbol | Description                                              | Reference |
|--------------------|----------------------------------------------------------|-----------|
| CMLB               | Inverts the bit data specified by (s), and store in (d). | Page 406  |
| CMLBP              |                                                          |           |

### ■Transferring 16-bit block data

| Instruction symbol | Description                                                                                             | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------|-----------|
| BMOV               | <br>(n) = 1 to 65535 | Page 407  |
| BMOVP              |                                                                                                         |           |

### ■Transferring identical 16-bit block data

| Instruction symbol | Description                                                                                             | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------|-----------|
| FMOV               | <br>(n) = 1 to 65535 | Page 409  |
| FMOVP              |                                                                                                         |           |

### ■Transferring identical 32-bit block data

| Instruction symbol | Description                                                                                             | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------|-----------|
| DFMOV              | <br>(n) = 1 to 65535 | Page 411  |
| DFMOVP             |                                                                                                         |           |

### ■Exchanging 16-bit/32-bit data

| Instruction symbol | Description                                 | Reference |
|--------------------|---------------------------------------------|-----------|
| XCH                | (d1) $\longleftrightarrow$ (d2)             | Page 413  |
| XCHP               |                                             |           |
| DXCH               | (d1+1, d1) $\longleftrightarrow$ (d2+1, d2) | Page 415  |
| DXCHP              |                                             |           |

## ■Exchanging the upper and lower bytes of 16-bit data

| Instruction symbol | Description | Reference |
|--------------------|-------------|-----------|
| SWAP               |             | Page 417  |
| SWAPP              |             |           |

## ■Exchanging the upper and lower bytes of 32-bit data

| Instruction symbol | Description | Reference |
|--------------------|-------------|-----------|
| DSWAP              |             | Page 418  |
| DSWAPP             |             |           |

## ■Transferring 1-bit data

| Instruction symbol | Description                                  | Reference |
|--------------------|----------------------------------------------|-----------|
| MOVB               | Stores the bit data specified by (s) in (d). | Page 419  |
| MOVBP              |                                              |           |

## ■Parallel run (octal mode) (16-bit data)

| Instruction symbol | Description                                                                                                   | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------|-----------|
| PRUN               | Handles device number specified by (s) in digit specification and (d) as octal, and stores into (d) from (s). | Page 420  |
| PRUNP              |                                                                                                               |           |

## ■Parallel run (octal mode) (32-bit data)

| Instruction symbol | Description                                                                                                   | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------|-----------|
| DPRUN              | Handles device number specified by (s) in digit specification and (d) as octal, and stores into (d) from (s). | Page 422  |
| DPRUNP             |                                                                                                               |           |

## ■Transferring n-bit data

| Instruction symbol | Description                                                                           | Reference |
|--------------------|---------------------------------------------------------------------------------------|-----------|
| BLKMOVB            | Block transfers bit data for (n) points from (s) to bit data for (n) points from (d). | Page 424  |
| BLKMOVBP           |                                                                                       |           |

## 3.3 Application Instruction

### Rotation instruction

#### ■Rotating 16-bit data to the right

| Instruction symbol | Description                                                                                                                  | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|-----------|
| ROR                | Rotates the 16-bit binary data to the right by (n) bit(s) (not including the carry flag).                                    | Page 426  |
| RORP               |  <p>(1)<br/>(1): (n) bit right rotation</p> |           |
| RCR                | Rotates the 16-bit binary data to the right by (n) bit(s) (including the carry flag).                                        |           |
| RCRP               |  <p>(1)<br/>(1): (n) bit right rotation</p> |           |

#### ■Rotating 16-bit data to the left

| Instruction symbol | Description                                                                                                                   | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|-----------|
| ROL                | Rotates the 16-bit binary data to the left by (n) bit(s) (not including the carry flag).                                      | Page 429  |
| ROLP               |  <p>(1)<br/>(1): (n) bit left rotation</p>  |           |
| RCL                | Rotates the 16-bit binary data to the left by (n) bit(s) (including the carry flag).                                          |           |
| RCLP               |  <p>(1)<br/>(1): (n) bit left rotation</p> |           |

#### ■Rotating 32-bit data to the right

| Instruction symbol | Description                                                                                                                    | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|-----------|
| DROR               | Rotates the 32-bit binary data to the right by (n) bit(s) (not including the carry flag).                                      | Page 432  |
| DRORP              |  <p>(1)<br/>(1): (n) bit right rotation</p> |           |
| DRCR               | Rotates the 32-bit binary data to the right by (n) bit(s) (including the carry flag).                                          |           |
| DRCRP              |  <p>(1)<br/>(1): (n) bit right rotation</p> |           |

## ■Rotating 32-bit data to the left

| Instruction symbol | Description                                                                                                                            | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|-----------|
| DROL               | Rotates the 32-bit binary data to the left by (n) bit(s) (not including the carry flag).                                               | Page 434  |
| DROL P             | (SM700, SM8022)<br> <p>(1): (n) bit left rotation</p> |           |
| DRCL               | Rotates the 32-bit binary data to the left by (n) bit(s) (including the carry flag).                                                   |           |
| DRCL P             | (SM700, SM8022)<br> <p>(1): (n) bit left rotation</p> |           |

## Program branch instruction

### ■Pointer branch

| Instruction symbol | Description                                          | Reference |
|--------------------|------------------------------------------------------|-----------|
| CJ                 | When the input condition is met, jump to pointer (P) | Page 436  |
| CJP                |                                                      |           |

### ■Jumping to END

| Instruction symbol | Description                                              | Reference |
|--------------------|----------------------------------------------------------|-----------|
| GOEND              | When the input condition is met, jump to END instruction | Page 440  |

## Program execution control instruction

### ■Disabling/enabling interrupt programs

| Instruction symbol | Description                                                 | Reference |
|--------------------|-------------------------------------------------------------|-----------|
| DI                 | Disables the execution of interrupt programs.               | Page 441  |
| EI                 | Releases the execution disabled state of interrupt program. |           |

### ■Disabling the interrupt program with specified priority or lower

| Instruction symbol | Description                                                                                                                     | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|-----------|
| DI                 | Disables the execution of the interrupt program with a priority specified by (s) or lower until the EI instruction is executed. | Page 443  |

### ■Interrupt program mask

| Instruction symbol | Description                       | Reference |
|--------------------|-----------------------------------|-----------|
| IMASK              | Interrupt disable/enable settings | Page 447  |

### ■Disabling/enabling the specified interrupt pointer

| Instruction symbol | Description                                             | Reference |
|--------------------|---------------------------------------------------------|-----------|
| SIMASK             | Disables/enables the interrupt pointer specified by (I) | Page 449  |

### ■Returning from the interrupt program

| Instruction symbol | Description                                                | Reference |
|--------------------|------------------------------------------------------------|-----------|
| IRET               | Returns from the interrupt program to the sequence program | Page 451  |

### ■Resetting the watchdog timer

| Instruction symbol | Description                                    | Reference |
|--------------------|------------------------------------------------|-----------|
| WDT                | Resets the watchdog timer (WDT) in the program | Page 454  |
| WDTP               |                                                |           |

## Structuring instruction

### ■Performing the FOR to NEXT instruction loop

| Instruction symbol | Description                                                                     | Reference |
|--------------------|---------------------------------------------------------------------------------|-----------|
| FOR                | Execute the instructions between FOR instruction and NEXT instruction (n) times | Page 455  |
| NEXT               |                                                                                 |           |

### ■Forcibly terminating the FOR to NEXT instruction loop

| Instruction symbol | Description                                                                                  | Reference |
|--------------------|----------------------------------------------------------------------------------------------|-----------|
| BREAK              | Forcibly end execution between FOR instruction and NEXT instruction, and jump to pointer (P) | Page 458  |
| BREAKP             |                                                                                              |           |

### ■Calling a subroutine program

| Instruction symbol | Description                                                                     | Reference |
|--------------------|---------------------------------------------------------------------------------|-----------|
| CALL               | Executes a subroutine program specified by (P) when the input condition is met. | Page 460  |
| CALLP              |                                                                                 |           |

### ■Returning from the subroutine program

| Instruction symbol | Description                          | Reference |
|--------------------|--------------------------------------|-----------|
| RET                | Returns from the subroutine program. | Page 465  |
| SRET               |                                      |           |

### ■Calling a subroutine program

| Instruction symbol | Description                                                                                                                                                                              | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| XCALL              | Executes a subroutine program specified by (P) when the input condition is met.<br>Carry out non-execution processing for the subroutine program (P), when input conditions are not met. | Page 466  |

## Data table operation instruction

### ■Reading the oldest data from the data table

| Instruction symbol | Description                                                                                           | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------|-----------|
| SFRD               |  <p>P: Pointer</p> | Page 468  |
| SFRDP              |                                                                                                       |           |

### ■Reading the newest data from the data table

| Instruction symbol | Description                                                                                           | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------|-----------|

## Reading/writing data instructions

### ■Reading data from the data memory

| Instruction symbol | Description                                                  | Reference |
|--------------------|--------------------------------------------------------------|-----------|
| S.DEVLD            | Reads data from the device data storage file in data memory. | Page 481  |
| SP.DEVLD           |                                                              |           |

### ■Writing data to the data memory

| Instruction symbol | Description                                                                                   | Reference |
|--------------------|-----------------------------------------------------------------------------------------------|-----------|
| SP.DEVST           | Writes the specified number of points of data to the device data storage file in data memory. | Page 483  |

## File operation instructions

### ■Reading data from the specified file

| Instruction symbol | Processing details                  | Reference |
|--------------------|-------------------------------------|-----------|
| SP.FREAD           | Reads data from the specified file. | Page 486  |

### ■Writing data to the specified file

| Instruction symbol | Processing details                 | Reference |
|--------------------|------------------------------------|-----------|
| SP.FWRITE          | Writes data to the specified file. | Page 512  |

### ■Deleting the specified file

| Instruction symbol | Processing details                    | Reference |
|--------------------|---------------------------------------|-----------|
| SP.FDELETE         | Deletes the specified file or folder. | Page 535  |

### ■Copying the specified file

| Instruction symbol | Processing details                   | Reference |
|--------------------|--------------------------------------|-----------|
| SP.FCOPY           | Copies the specified file or folder. | Page 543  |

### ■Moving the specified file

| Instruction symbol | Processing details                  | Reference |
|--------------------|-------------------------------------|-----------|
| SP.FMOVE           | Moves the specified file or folder. | Page 553  |

### ■Renaming the specified file

| Instruction symbol | Processing details                    | Reference |
|--------------------|---------------------------------------|-----------|
| SP.FRENAME         | Renames the specified file or folder. | Page 563  |

### ■Acquiring the status of the specified file

| Instruction symbol | Processing details                                   | Reference |
|--------------------|------------------------------------------------------|-----------|
| SP.FSTATUS         | Acquires the status of the specified file or folder. | Page 571  |

## Extended file register operation instruction

### ■Reading extended file register

| Instruction symbol | Description                                                                                                     | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------|-----------|
| ERREAD             | Reads the current value of the extended file register (ER) to the file register (R) in the CPU built-in memory. | Page 580  |

### ■Writing extended file register

| Instruction symbol | Description                                                                                                      | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------|-----------|
| ERWRITE            | Writes the current value of the file register (R) in the CPU built-in memory to the extended file register (ER). | Page 583  |

### ■Batch initialization function of extended file register

| Instruction symbol | Description                                                              | Reference |
|--------------------|--------------------------------------------------------------------------|-----------|
| ERINIT             | Initialize all the points of the extended file register (ER) in a batch. | Page 586  |

## Character string operation instruction

### ■Comparing character strings

| Instruction symbol      | Description                                                                                                                                                                                                                                    | Reference |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| LD\$=, AND\$=, OR\$=    | Compares the character string (s1) with the character string (s2) one character at a time.*1<br>[Character string (s1)] = [Character string (s2)]: Conductive state<br>[Character string (s1)] ≠ [Character string (s2)]: Non-Conductive state | Page 589  |
| LD\$<>, AND\$<>, OR\$<> | Compares the character string (s1) with the character string (s2) one character at a time.*1<br>[Character string (s1)] ≠ [Character string (s2)]: Conductive state<br>[Character string (s1)] = [Character string (s2)]: Non-Conductive state |           |
| LD\$>, AND\$>, OR\$>    | Compares the character string (s1) with the character string (s2) one character at a time.*1<br>[Character string (s1)] > [Character string (s2)]: Conductive state<br>[Character string (s1)] ≤ [Character string (s2)]: Non-Conductive state |           |
| LD\$≤, AND\$≤, OR\$≤    | Compares the character string (s1) with the character string (s2) one character at a time.*1<br>[Character string (s1)] ≤ [Character string (s2)]: Conductive state<br>[Character string (s1)] > [Character string (s2)]: Non-Conductive state |           |
| LD\$<, AND\$<, OR\$<    | Compares the character string (s1) with the character string (s2) one character at a time.*1<br>[Character string (s1)] < [Character string (s2)]: Conductive state<br>[Character string (s1)] ≥ [Character string (s2)]: Non-Conductive state |           |
| LD\$≥, AND\$≥, OR\$≥    | Compares the character string (s1) with the character string (s2) one character at a time.*1<br>[Character string (s1)] ≥ [Character string (s2)]: Conductive state<br>[Character string (s1)] < [Character string (s2)]: Non-Conductive state |           |

\*1 The following shows comparison conditions for comparing character strings.

- Match: All characters in the strings must match
- Larger string: In case of different character strings, character string with the larger character code  
(If character string lengths are different, the longer character string)
- Smaller string: In case of different character strings, character string with the smaller character code  
(If character string lengths are different, the shorter character string)

### ■Concatenating character strings

| Instruction symbol | Description                                                                                                            | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------|-----------|
| \$+                | • In case of 2 operands                                                                                                | Page 592  |
| \$+P               | Connect the character string specified by (s) to the end of the character string specified by (d), and store in (d).   |           |
| \$+                | • In case of 3 operands                                                                                                | Page 594  |
| \$+P               | Connect the character string specified by (s2) to the end of the character string specified by (s1), and store in (d). |           |

### ■Transferring character strings

| Instruction symbol | Description                                                                                                      | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------|-----------|
| \$MOV              | Transfer the character strings specified by (s) to the devices specified by (d) onwards.                         | Page 596  |
| \$MOVP             |                                                                                                                  |           |
| \$MOV_WS           | Transfers the Unicode character strings in the device specified by (s) to the device specified by (d) and later. | Page 598  |
| \$MOVP_WS          |                                                                                                                  |           |

### ■Converting 16-bit/32-bit binary data to decimal ASCII

| Instruction symbol | Description                                                                                                                                      | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| BINDA              | Converts the 1 word binary value specified by (s) to 5 digits decimal ASCII value, and stores in the word device specified by (d).               | Page 600  |
| BINDAP             |                                                                                                                                                  |           |
| BINDA_U            |                                                                                                                                                  |           |
| BINDAP_U           |                                                                                                                                                  |           |
| DBINDA             | Converts the 2 word binary value specified by (s) to 10 digits decimal ASCII value, and stores in the word device area specified by (d) onwards. | Page 605  |
| DBINDAP            |                                                                                                                                                  |           |
| DBINDA_U           |                                                                                                                                                  |           |
| DBINDAP_U          |                                                                                                                                                  |           |

## ■Converting HEX code data to ASCII

| Instruction symbol | Description                                                                                                                             | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|-----------|
| ASCI               | Converts the (n) characters within the HEX code data specified by (s) to ASCII, and stores in the device area specified by (d) onwards. | Page 611  |
| ASCIP              |                                                                                                                                         |           |

## ■Converting 16-bit/32-bit binary data to character string

| Instruction symbol | Description                                                                                                                                                                                                                                | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| STR                | Converts the 1 word binary value specified by (s2) to the decimal character string with total number of digits and the number of digits in the decimal fraction part as specified in (s1), and stores this in the device specified by (d). | Page 615  |
| STRP               |                                                                                                                                                                                                                                            |           |
| STR_U              |                                                                                                                                                                                                                                            |           |
| STRP_U             |                                                                                                                                                                                                                                            |           |
| DSTR               | Convert the 2 word binary value specified by (s2) to the decimal character string with total number of digits and the number of digits in the decimal fraction part as specified in (s1), and stores this in the device specified by (d).  | Page 618  |
| DSTRP              |                                                                                                                                                                                                                                            |           |

| SJIS2WSB           | Converts the shift JIS character string in the device specified by (s) to the Unicode character string, add a byte order mark to the head of the converted data, and stores it in the device specified by (d). | Page 634  |
| SJIS2WSBP          |                                                                                                                                                                                                                |           |

## ■Detecting a character string length

| Instruction symbol | Description                                                                                                          | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------|-----------|
| LEN                | Stores the length of the character string data stored in the device specified by (s) in the device specified by (d). | Page 637  |
| LENP               |                                                                                                                      |           |

## ■Extracting character string data from the right/left

| Instruction symbol | Description                                                                                                                 | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|-----------|
| RIGHT              | Stores the (n) characters from the last character of the character string specified by (s) in the device specified by (d).  | Page 639  |
| RIGHTP             |                                                                                                                             |           |
| LEFT               | Stores the (n) characters from the first character of the character string specified by (s) in the device specified by (d). | Page 642  |
| LEFTP              |                                                                                                                             |           |

## ■ Storing/replacing the specified number of character strings

| Instruction symbol | Description                                                                                                                                  | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| MIDR               | Stores the specified number of characters from the position specified by (s2) of the character string (s1) into the device specified by (d). | Page 645  |
| MIDRP              |                                                                                                                                              |           |
| MIDW               | Stores the specified number of characters from the character string (s1) into the location specified by (s2) of the character string (d).    | Page 648  |
| MIDWP              |                                                                                                                                              |           |

## ■ Searching character string

| Instruction symbol | Description                                                                                                                                                                                                                   | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| INSTR              | Searches the character string in the device specified by (s2), starting from the (s3)th character, for the character string in the device specified by (s1), and stores the matching location in the device specified by (d). | Page 652  |
| INSTRP             |                                                                                                                                                                                                                               |           |

## ■ Inserting character string

| Instruction symbol | Description                                                                                                                                                 | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| STRINS             | Inserts the character string data specified in (s1) at the position (s2)(Insert position) from the beginning of the character string data specified by (d). | Page 655  |
| STRINSP            |                                                                                                                                                             |           |

## ■ Deleting character string

| Instruction symbol | Description                                                                                                                                                             | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| STRDEL             | From the head of the character string data specified in (d), delete (n2) characters from the location specified as the character number (n1) (deletion start location). | Page 657  |
| STRDELP            |                                                                                                                                                                         |           |

## Real number instruction

### ■ Comparing single-precision real numbers

| Instruction symbol   | Description                                                                                                                                            | Reference |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| LDE=, ANDE=, ORE=    | [[s1]+1, (s1)] = [(s2)+1, (s2)]: Conductive<br>[[s1]+1, (s1)] ≠ [(s2)+1, (s2)]: Non-Conductive                                                         | Page 659  |
| LDE<>, ANDE<>, ORE<> | [[s1]+1, (s1)] ≠ [(s2)+1, (s2)]: Conductive<br>[[s1]+1, (s1)] = [(s2)+1, (s2)]: Non-Conductive                                                         |           |
| LDE>, ANDE>, ORE>    | [[s1]+1, (s1)] > [(s2)+1, (s2)]: Conductive<br>[[s1]+1, (s1)] ≤ [(s2)+1, (s2)]: Non-Conductive                                                         |           |
| LDE≤, ANDE≤, ORE≤    | [[s1]+1, (s1)] ≤ [(s2)+1, (s2)]: Conductive<br>[[s1]+1, (s1)] > [(s2)+1, (s2)]: Non-Conductive                                                         |           |
| LDE<, ANDE<, ORE<    | [[s1]+1, (s1)] < [(s2)+1, (s2)]: Conductive<br>[[s1]+1, (s1)] ≥ [(s2)+1, (s2)]: Non-Conductive                                                         |           |
| LDE≥, ANDE≥, ORE≥    | [[s1]+1, (s1)] ≥ [(s2)+1, (s2)]: Conductive<br>[[s1]+1, (s1)] < [(s2)+1, (s2)]: Non-Conductive                                                         |           |
| DECMP                | This instruction compares two data values (single-precision real numbers), and outputs the result (larger, smaller or equal) to three bit devices.     | Page 661  |
| DECMPP               |                                                                                                                                                        |           |
| DEZCP                | This instruction compares two data values (single-precision real numbers), and outputs the result (larger, smaller or data band) to three bit devices. | Page 663  |
| DEZCPP               |                                                                                                                                                        |           |

## ■Adding/subtracting single-precision real numbers

| Instruction symbol | Description                                                                                                                        | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|-----------|
| E+                 | <ul style="list-style-type: none"> <li>In case of 2 operands</li> </ul> $[(d)+1, (d)] + [(s)+1, (s)] \rightarrow [(d)+1, (d)]$     | Page 665  |
| E+P                |                                                                                                                                    |           |

## ■Searching the maximum value of single-precision real number

| Instruction symbol | Description                                                                                                                                                                                                                                   | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| EMAX               | These instructions search for the maximum value in the (n) points of single-precision real number block data specified by the device starting from the one specified by (s), and store the maximum value in the device area specified by (d). | Page 730  |
| EMAXP              |                                                                                                                                                                                                                                               |           |

## ■Searching the minimum value of single-precision real number

| Instruction symbol | Description                                                                                                                                                                                                                                    | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| EMIN               | These instructions search for the minimum value in the (n) points of single-precision real number block data specified by the device starting from the one specified by (s), and store the minimum value in the device areas specified by (d). | Page 732  |
| EMINP              |                                                                                                                                                                                                                                                |           |

## Random number instruction

### ■Generating random number

| Instruction symbol | Description                                                                                | Reference |
|--------------------|--------------------------------------------------------------------------------------------|-----------|
| RND                | Generates a random number from 0 to 32767, and stores this in the device specified by (d). | Page 734  |
| RNDP               |                                                                                            |           |

## Index register operation instruction

### ■Saving/returning all data of the index register

| Instruction symbol | Description                                                                    | Reference |
|--------------------|--------------------------------------------------------------------------------|-----------|
| ZPUSH              | Saves the contents of index registers to the devices specified by (d) onwards. | Page 736  |
| ZPUSHP             |                                                                                |           |
| ZPOP               | Reads the data in devices specified by (d) onwards to the index registers.     | Page 739  |
| ZPOPP              |                                                                                |           |

### ■Saving/returning the selected data of the index register and long index register

| Instruction symbol | Description                                                                                                                           | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|-----------|
| ZPUSH              | Saves the contents of the index registers and long index registers in the range specified by (s) to devices specified by (d) onwards. | Page 740  |
| ZPUSHP             |                                                                                                                                       |           |
| ZPOP               | Reads data in the devices specified by (d) onwards to the index registers and long index registers.                                   | Page 742  |
| ZPOPP              |                                                                                                                                       |           |

## Data control instruction

### ■Upper and lower limit control of 16-bit/32-bit binary data

| Instruction symbol | Description                                                                                                                                                                                                                                                                        | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| LIMIT              | (s3) < (s1): The (s1) value is stored in (d)<br>(s1) ≤ (s3) ≤ (s2): The (s3) value is stored in (d)<br>(s2) < (s3): The (s2) value is stored in (d)                                                                                                                                | Page 743  |

## Special timer instruction

### ■Teaching timer

| Instruction symbol | Description                                                                                                                                    | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| TTMR               | $(T_{ON}) \times (s) \longrightarrow (d)$ <p> <math>(s)=0:1, (s)=1:10, (s)=2:100</math><br/> <math>T_{ON}</math>: On time of TTMR         </p> | Page 769  |

### ■Special function timer

| Instruction symbol | Description                                                                                                                                                                                                                                                                                                                                                                                     | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| STMR               | <p>The 4 points from the bit device specified by (d) operate as shown below, depending on the ON/OFF status of the input conditions for the STMR instruction:</p> <p>           (d)+0: Off delay timer output<br/>           (d)+1: One shot after off timer output<br/>           (d)+2: One shot after on timer output<br/>           (d)+3: On delay and off delay timer output         </p> | Page 772  |

## Special counter instruction

### ■Signed 32-bit bi-directional counters

| Instruction symbol | Description                                                                                                                                                                                                                                                                                                                                                                                      | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| UDCNTF             | <p>This instruction increments the current value of the counter specified by (d) by 1 when the operation result up to UDCNTF instruction changes from OFF to ON, and when the counter reaches the end of its count, NO contact becomes turns ON and NC contact becomes turns OFF. When the long counter specified by (d) is a high-speed counter, up-counting and down-counting are enabled.</p> | Page 774  |

## Shortcut control instruction

### ■Rotary table shortest direction control

| Instruction symbol | Description                                                                                                                            | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|-----------|
| ROTC               | <p>Rotates a rotary table with (n1) divisions from the stop position to the position specified by (s)+1 in the shortest direction.</p> | Page 776  |

## Ramp signal instruction

### ■Ramp signal

| Instruction symbol | Description                                                                                                                                                      | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| RAMPF              | <p>Shifts the value from the one specified by (s1) to the one specified by (s2) in (n) scans. The current value is stored in the device specified by (d1)+0.</p> | Page 779  |

## Pulse related instruction

### ■Measuring the density of 16 bit binary/32 bit binary pulses

| Instruction symbol | Description                                                                                                                                               | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| SPD                | Counts the pulse input from the device specified by (s1) for the duration of time specified by (s2), and stores the count in the device specified by (d). | Page 782  |
| DSPD               |                                                                                                                                                           | Page 788  |

### ■16 bit binary/32 bit binary pulse output

| Instruction symbol | Description                                                                                                                                                                                                        | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| PLSY               | • When an FX3 compatible operand is specified<br>This instruction outputs a pulse at a frequency specified by (s) for the number of times specified by (n) from the output number (Y) specified by (d).            | Page 793  |
| DPLSY              | • When an FX5 compatible operand is specified<br>This instruction outputs a pulse at a frequency specified by (s) for the number of times specified by (n), from the output number (axis number) specified by (d). | Page 801  |

### ■16 bit binary/32 bit binary pulse width modulation

| Instruction symbol | Description                                                                                                                    | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|-----------|
| PWM                | Outputs the pulse of the cycle specified by (s2), for the ON time on specified by (s1), to the output number specified by (d). | Page 809  |
| DPWM               |                                                                                                                                | Page 816  |

## Input matrix instruction

### ■Input matrix

| Instruction symbol | Description                                                                                      | Reference |
|--------------------|--------------------------------------------------------------------------------------------------|-----------|
| MTR                | Reads matrix input as 8-point input × "n"-point output (transistor) in the time division method. | Page 823  |

## Initial State

### ■Initial State

| Instruction symbol | Description                                                                           | Reference |
|--------------------|---------------------------------------------------------------------------------------|-----------|
| IST                | Automatically controls the initial state and special relays in a step ladder program. | Page 827  |

## Drum sequence

### ■16-bit binary data absolute method

| Instruction symbol | Description                                                                   | Reference |
|--------------------|-------------------------------------------------------------------------------|-----------|
| ABSD               | Creates many output patterns corresponding to the current value of a counter. | Page 838  |

### ■32-bit binary data absolute method

| Instruction symbol | Description                                                                   | Reference |
|--------------------|-------------------------------------------------------------------------------|-----------|
| DABSD              | Creates many output patterns corresponding to the current value of a counter. | Page 840  |

### ■Relative method

| Instruction symbol | Description                                                                                                                                                                                                                                                                                                         | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| INCD               | This instruction compares the current value of a counter with the data table having (n) lines starting from (s1) (which occupies (n) lines × 1 device). If the counter value is equivalent to the table data, the current output is reset, and the ON/OFF status of the specified sequential outputs is controlled. | Page 842  |

## Check code

### ■Check code

| Instruction symbol | Description                                                                                                                                                                                 | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| CCD                | This instruction calculates the sum data and horizontal parity value of data stored in (s) to (s)+(n)-1. The sum data is stored in (d), and the horizontal parity value is stored in (d)+1. | Page 845  |
| CCDP               |                                                                                                                                                                                             |           |

## Data operation instruction

### ■Searching 16-bit/32-bit data

| Instruction symbol | Description                                                                                                                        | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|-----------|
| SERMM              | Searches for data same as (s2) in (s1).                                                                                            | Page 848  |
| SERMMP             |  <p>(d) to (d)+4: Search result</p>               |           |
| DSERMM             | Searches for data same as (s2) in (s1).                                                                                            | Page 850  |
| DSERMMP            |  <p>(d)+1, (d) to (d)+9, (d)+8: Search result</p> |           |

### ■Bit check of 16-bit/32-bit data

| Instruction symbol | Description                                                                                                       | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------------------|-----------|
| SUM                |  <p>(d): Total number of 1s</p>  | Page 852  |
| SUMP               |                                                                                                                   |           |

## Timing check instruction

### ■Generating timing pulses

| Instruction symbol | Description                                                                               | Reference |
|--------------------|-------------------------------------------------------------------------------------------|-----------|
| DUTY               | <p>(d): SM420 to SM424, SM2330 to SM2334</p> <p>(n1): (n1) scans<br/>(n2): (n2) scans</p> | Page 923  |

### ■Hour meter

| Instruction symbol | Description                                                                                                                                                                                                                                                                                                                                                                                                | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| HOURM              | This instruction adds the time during which the input contact is ON in units of 1 hour, turns ON the device specified by (d2) when the total ON time exceeds the time specified by (s) (16-bit binary data), and stores the current value in units of 1 hour (16-bit binary data) to (d1), and the current value that is less than one hour (16-bit binary data) to (d1)+1 in units of seconds.            | Page 926  |
| DHOURM             | This instruction adds the time during which the input contact is ON in units of 1 hour, turns ON the device specified by (d2) when the total ON time exceeds the time specified by (s) (32-bit binary data), and stores the current value in units of 1 hour (32-bit binary data) to (d1)+1 and (d1), and the current value that is less than one hour (16-bit binary data) to (d1)+2 in units of seconds. | Page 928  |

## Module access instruction

### ■Performing I/O refresh

| Instruction symbol | Description                                                     | Reference |
|--------------------|-----------------------------------------------------------------|-----------|
| REF                | This instruction refreshes the relevant I/O area during a scan. | Page 930  |
| REFP               |                                                                 |           |
| RFS                |                                                                 |           |
| RFSP               |                                                                 |           |

### ■Reading 1-word/2-word data from another module (16-bit specification)

| Instruction symbol | Description                                                                                            | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------|-----------|
| FROM               | These instructions read the (n) word data from the buffer memory of the intelligent function module.   | Page 932  |
| FROMP              |                                                                                                        |           |
| DFROM              | These instructions read the (n)×2 word data from the buffer memory of the intelligent function module. |           |
| DFROMP             |                                                                                                        |           |

### ■Writing 1-word/2-word data to another module (16-bit specification)

| Instruction symbol | Description                                                                                           | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------|-----------|
| TO                 | These instructions write the (n) word data to the buffer memory of the intelligent function module.   | Page 936  |
| TOP                |                                                                                                       |           |
| DTO                | These instructions write the (n)×2 word data to the buffer memory of the intelligent function module. |           |
| DTOP               |                                                                                                       |           |

### ■Reading 1-word/2-word data from another module (32-bit specification)

| Instruction symbol | Description                                                                                            | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------|-----------|
| FROMD              | These instructions read the (n) word data from the buffer memory of the intelligent function module.   | Page 939  |
| FROMDP             |                                                                                                        |           |
| DFROMD             | These instructions read the (n)×2 word data from the buffer memory of the intelligent function module. |           |
| DFROMDP            |                                                                                                        |           |

### ■Writing 1-word/2-word data to another module (32-bit specification)

| Instruction symbol | Description                                                                                           | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------|-----------|
| TOD                | These instructions write the (n) word data to the buffer memory of the intelligent function module.   | Page 942  |
| TODP               |                                                                                                       |           |
| DTOD               | These instructions write the (n)×2 word data to the buffer memory of the intelligent function module. |           |
| DTODP              |                                                                                                       |           |

## Logging instructions

### ■Setting/resetting trigger logging

| Instruction symbol | Description                                                                                                                                                                                          | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| LOGTRG             | Generates a trigger for trigger logging. Data sampled for the number of records (specified in the trigger logging setting parameter using the engineering tool) are stored in the data logging file. | Page 945  |
| LOGTRGR            | Resets the trigger condition.                                                                                                                                                                        | Page 946  |

## Real-time monitor function instruction

| Instruction symbol | Description                                                                                 | Reference |
|--------------------|---------------------------------------------------------------------------------------------|-----------|
| RTM                | Monitors the data when the instruction is executed by using the real-time monitor function. | Page 947  |

## 3.4 Step Ladder Instructions

### Starts/Ends step ladder

| Instruction symbol | Description          | Reference |
|--------------------|----------------------|-----------|
| STL                | Start of step ladder | Page 949  |
| RETSTL             | End of step ladder   |           |

## 3.5 PID Control Instruction

### PID control loop

| Instruction symbol | Description                                                                                            | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------|-----------|
| PID                | This instruction executes PID control which changes the output value according to the input variation. | Page 953  |

## 3.6 SFC Program Instructions

### SFC control instructions

#### ■Checking the status of a step

| Instruction symbol | Description                                                                                                                                                                                                                    | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| LD [S□/BL□\S□]     | Outputs the status (active or inactive) of the specified step as the operation result. (Normally open contact instruction)                                                                                                     | Page 956  |
| LDI [S□/BL□\S□]    | Outputs the status (active or inactive) of the specified step as the operation result. (Normally closed contact instruction)                                                                                                   |           |
| AND [S□/BL□\S□]    | Performs an AND operation between the status (active or inactive) of the specified step and the previous operation result(s), and output the operation result. (Normally open contact series connection instruction)           |           |
| ANI [S□/BL□\S□]    | Performs an AND operation between the status (active or inactive) of the specified step and the previous operation result(s), and output the operation result. (Normally closed contact series connection instruction)         |           |
| OR [S□/BL□\S□]     | Performs an OR operation between the status (active or inactive) of the specified step and the previous operation result(s), and output the operation result. (Single normally open contact parallel connection instruction)   |           |
| ORI [S□/BL□\S□]    | Performs an OR operation between the status (active or inactive) of the specified step and the previous operation result(s), and output the operation result. (Single normally closed contact parallel connection instruction) |           |

#### ■Checking the status of a block

| Instruction symbol | Description                                                                                                                                                                                                                     | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| LD [BL□]           | Outputs the status (active or inactive) of the specified block as the operation result. (Normally open contact instruction)                                                                                                     | Page 958  |
| LDI [BL□]          | Outputs the status (active or inactive) of the specified block as the operation result. (Normally closed contact instruction)                                                                                                   |           |
| AND [BL□]          | Performs an AND operation between the status (active or inactive) of the specified block and the previous operation result(s), and output the operation result. (Normally open contact series connection instruction)           |           |
| ANI [BL□]          | Performs an AND operation between the status (active or inactive) of the specified block and the previous operation result(s), and output the operation result. (Normally closed contact series connection instruction)         |           |
| OR [BL□]           | Performs an OR operation between the status (active or inactive) of the specified block and the previous operation result(s), and output the operation result. (Single normally open contact parallel connection instruction)   |           |
| ORI [BL□]          | Performs an OR operation between the status (active or inactive) of the specified block and the previous operation result(s), and output the operation result. (Single normally closed contact parallel connection instruction) |           |

#### ■Batch-reading the status of steps

| Instruction symbol    | Description                                                                                                                                                                    | Reference |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| MOV [KnS□/BL□\KnS□]   | Batch-reads (in units of 16-bit binary data) the status (active or inactive) of steps in the specified block, and stores the read data in the specified device. (Kn: K1 to K4) | Page 960  |
| MOVP [KnS□/BL□\KnS□]  |                                                                                                                                                                                |           |
| DMOV [KnS□/BL□\KnS□]  | Batch-reads (in units of 32-bit binary data) the status (active or inactive) of steps in the specified block, and stores the read data in the specified device. (Kn: K1 to K8) | Page 963  |
| DMOVP [KnS□/BL□\KnS□] |                                                                                                                                                                                |           |
| BMOV [KnS□/BL□\KnS□]  | Batch-reads (in units of the specified number of words starting from the specified step) the status (active or inactive) of steps in the specified block. (Kn: K1 to K4)       | Page 966  |
| BMOVP [KnS□/BL□\KnS□] |                                                                                                                                                                                |           |

#### ■Starting a block

| Instruction symbol | Description                                                                                | Reference |
|--------------------|--------------------------------------------------------------------------------------------|-----------|
| SET [BL□]          | Activates the specified block, and executes a step sequence starting from an initial step. | Page 970  |

#### ■Ending a block

| Instruction symbol | Description                      | Reference |
|--------------------|----------------------------------|-----------|
| RST [BL□]          | Deactivates the specified block. | Page 971  |

## ■Pausing a block

| Instruction symbol | Description                                                 | Reference |
|--------------------|-------------------------------------------------------------|-----------|
| PAUSE [BL□]        | Temporarily stops the step sequence in the specified block. | Page 972  |

## ■Restarting a block

| Instruction symbol | Description                                                                                                                 | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|-----------|
| RSTART [BL□]       | Releases the temporary stop, and restarts the sequence from the step where the sequence was stopped in the specified block. | Page 974  |

## ■Activating a step

| Instruction symbol | Description                   | Reference |
|--------------------|-------------------------------|-----------|
| SET [S□/BL□\S□]    | Activates the specified step. | Page 976  |

## ■Deactivating a step

| Instruction symbol | Description                     | Reference |
|--------------------|---------------------------------|-----------|
| RST [S□/BL□\S□]    | Deactivates the specified step. | Page 978  |

## ■Activating/deactivating a step

| Instruction symbol | Description                                                   | Reference |
|--------------------|---------------------------------------------------------------|-----------|
| OUT [S□/BL□\S□]    | This instruction activates or deactivates the specified step. | Page 980  |

## ■Batch-deactivating a step

| Instruction symbol | Description                                         | Reference |
|--------------------|-----------------------------------------------------|-----------|
| ZRST [S□/BL□\S□]   | Batch-deactivates the steps in the specified range. | Page 982  |
| ZRSTP [S□/BL□\S□]  |                                                     |           |

## SFC dedicated instruction

### ■Creating a dummy transition condition

| Instruction symbol | Description                                            | Reference |
|--------------------|--------------------------------------------------------|-----------|
| TRAN               | A dummy output which satisfies a transition condition. | Page 984  |

# 4 MODULE SPECIFIC INSTRUCTION

## 4.1 Network Common Instruction

### Link dedicated instruction

#### ■Reading data from another station programmable controller

| Instruction symbol | Description                                                   | Reference |
|--------------------|---------------------------------------------------------------|-----------|
| GP.READ            | Reads data from another station PLC device in units of words. | Page 988  |

#### ■Reading data from another station programmable controller (with notification)

| Instruction symbol | Description                                                                                                                                                                                                                                                      | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| GP.SREAD           | Reads data from another station PLC device in units of words.<br>When reading data has finished, a device of the other station is turned on.<br>(This makes it possible for the other station to recognize that data has been read by the GP.SREAD instruction.) | Page 994  |

#### ■Writing data to another station programmable controller

| Instruction symbol | Description                                                  | Reference |
|--------------------|--------------------------------------------------------------|-----------|
| GP.WRITE           | Writes data to another station PLC device in units of words. | Page 1000 |

#### ■Writing data to another station programmable controller (with notification)

| Instruction symbol | Description                                                                                                                                                                                                                                                         | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| GP.SWRITE          | Writes data to another station PLC device in units of words.<br>When writing data has finished, a device in the other station is turned on.<br>(This makes it possible for the other station to recognize that data has been written by the GP.SWRITE instruction.) | Page 1008 |

#### ■Sending data to another station programmable controller

| Instruction symbol | Description                        | Reference |
|--------------------|------------------------------------|-----------|
| GP.SEND            | Sends data to another station PLC. | Page 1016 |

#### ■Receiving data from another station programmable controller

| Instruction symbol | Description                                                                  | Reference |
|--------------------|------------------------------------------------------------------------------|-----------|
| GP.RECV            | Reads data received from another station PLC. (For the main routine program) | Page 1024 |

## 4.2 Ethernet Instruction

### Built-in Ethernet function instruction

#### ■Opening a connection

| Instruction symbol | Description                                              | Reference |
|--------------------|----------------------------------------------------------|-----------|
| SP.SOCOPEN         | This instruction opens the connection specified by (s1). | Page 1030 |

#### ■Closing a connection

| Instruction symbol | Description                                                                      | Reference |
|--------------------|----------------------------------------------------------------------------------|-----------|
| SP.SOCCLOSE        | This instruction closes the connection specified by (s1). (Closing a connection) | Page 1033 |

### Socket communication function instruction

#### ■Reading receive data during the END processing

| Instruction symbol | Description                                                                                                                                              | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| SP.SOCCRV          | This instruction reads the received data of the connection specified by (s1) from the socket communication receive data area, during the END processing. | Page 1035 |

## ■Sending data

| Instruction symbol | Description                                                                                           | Reference |
|--------------------|-------------------------------------------------------------------------------------------------------|-----------|
| SP.SOCSND          | This instruction sends the data set in (s3) to the target device of the connection specified by (s1). | Page 1038 |

## ■Reading connection information

| Instruction symbol | Description                                                                            | Reference |
|--------------------|----------------------------------------------------------------------------------------|-----------|
| SP.SOCCINF         | This instruction reads the connection information of the connection specified by (s1). | Page 1041 |

## ■Reading socket communication receive data

| Instruction symbol | Description                                                                                                                                                                                                        | Reference |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| S.SOCRDATA         | This instruction reads the data of the number of words specified in (n) from the socket communication receive data area of the connection specified by (s1), and stores it to the device specified by (d) onwards. | Page 1043 |
| SP.SOCRDATA        |                                                                                                                                                                                                                    |           |

## Predefined Protocol Support Function Instruction

### ■Executing the protocols registered for the predefined protocol support function

| Instruction symbol | Description                                                                                         | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------|-----------|
| SP.ECPRTCL         | Executes the protocol specified by the communication protocol support tool of the engineering tool. | Page 1045 |

## SLMP frame send instruction

### ■Sending the SLMP frame

| Instruction symbol | Description                                       | Reference |
|--------------------|---------------------------------------------------|-----------|
| SP.SLMPSND         | Sends SLMP messages to an SLMP-compatible device. | Page 1049 |

## File transfer function instruction

### ■Sending FTP client files

| Instruction symbol | Description                                                                             | Reference |
|--------------------|-----------------------------------------------------------------------------------------|-----------|
| SP.FTPPUT          | Sends the CPU module file specified in (s2) to the FTP server folder specified in (s3). | Page 1054 |

### ■Retrieving FTP client files

| Instruction symbol | Processing details                                                                                                                | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|-----------|
| SP.FTPGET          | Retrieves files on the FTP server, which are specified by (s2), to the folder path of the CPU module, which is specified by (s3). | Page 1059 |

## Ethernet module

### ■Opening a connection

| Instruction symbol | Description                                                                                       | Reference |
|--------------------|---------------------------------------------------------------------------------------------------|-----------|
| GP.OPEN            | This instruction establishes (opens) a connection with an external device for data communication. | Page 1064 |

### ■Closing a connection

| Instruction symbol | Description                                                                                              | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------|-----------|
| GP.CLOSE           | This instruction disconnects (closes) the connection from the external device during data communication. | Page 1067 |

### ■Reading receive data

| Instruction symbol | Description                                                                                 | Reference |
|--------------------|---------------------------------------------------------------------------------------------|-----------|
| GP.SOCCRCV         | This instruction reads receive data from the external device through socket communications. | Page 1069 |

### ■Sending data

| Instruction symbol | Description                                                                      | Reference |
|--------------------|----------------------------------------------------------------------------------|-----------|
| GP.SOCSND          | This instruction sends data to the external device through socket communications | Page 1071 |

## 4.3 CC-Link IE TSN Instructions

### Own station number/IP address setting

| Instruction symbol | Description                                                            | Reference |
|--------------------|------------------------------------------------------------------------|-----------|
| G.UINI             | Sets the station number and IP address for FX5-CCLGN-MS (own station). | Page 1073 |
| GP.UINI            |                                                                        |           |

### Sending an SLMP Frame

| Instruction symbol | Description                                                              | Reference |
|--------------------|--------------------------------------------------------------------------|-----------|
| G.SLMPSND          | Sends an SLMP message to the SLMP-compatible device on the same network. | Page 1076 |
| GP.SLMPSND         |                                                                          |           |

4

## 4.4 CC-Link IE Field Network Instruction

### Setting parameters

| Instruction symbol | Description                                                                                                                                                                                                                                                                                                                  | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| G.CCPASET          | Sets parameters in the FX5-CCLIEF (own station).                                                                                                                                                                                                                                                                             | Page 1085 |
| GP.CCPASET         | Use the G(P).CCPASET instruction to set parameters in the following cases. <ul style="list-style-type: none"><li>• If you want to change parameters without resetting the CPU module</li><li>• If you want to mount more intelligent device station modules than the number of modules set by the engineering tool</li></ul> |           |

### Setting the station number to own station

| Instruction symbol | Description                                              | Reference |
|--------------------|----------------------------------------------------------|-----------|
| G.UINI             | Sets the station number in the FX5-CCLIEF (own station). | Page 1088 |
| GP.UINI            |                                                          |           |

## 4.5 High-speed Counter Instruction

### High-speed processing instruction

#### ■Setting 32-bit data comparison

| Instruction symbol | Description                                                                                                                                        | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| DHSCS              | Turns ON the bit device of (d) when the current value of the high-speed counter of CH specified by (s2) is changed to the value specified by (s1). | Page 1091 |

#### ■Reset 32-bit data comparison

| Instruction symbol | Description                                                                                                                                         | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| DHSCR              | Turns OFF the bit device of (d) when the current value of the high-speed counter of CH specified by (s2) is changed to the value specified by (s1). | Page 1094 |

#### ■Comparison of 32-bit data band

| Instruction symbol | Description                                                                                                                  | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|-----------|
| DHSZ               | Compares whether the current value of the high-speed counter is within or outside the value range specified by (s1) or (s2). | Page 1097 |

#### ■Start/stop of the 16-bit/32-bit data high-speed I/O function

| Instruction symbol | Description                                        | Reference |
|--------------------|----------------------------------------------------|-----------|
| HIOEN              | Start or stop high-speed I/O for the specified CH. | Page 1100 |
| HIOENP             |                                                    |           |
| DHIOEN             |                                                    | Page 1104 |
| DHIOENP            |                                                    |           |

### High-speed current value transfer instruction

#### ■High-speed current value transfer of 16-bit/32-bit data

| Instruction symbol | Description                                        | Reference |
|--------------------|----------------------------------------------------|-----------|
| HCMOV              | Transfers the current value of the high-speed I/O. | Page 1108 |
| HCMOVP             |                                                    |           |
| DHCMOV             |                                                    | Page 1110 |
| DHCMOVP            |                                                    |           |

## 4.6 External Device Communication Instruction

### Serial communication 2

| Instruction symbol | Description                                        | Reference |
|--------------------|----------------------------------------------------|-----------|
| RS2                | Sends/receives data by non-protocol communication. | Page 1113 |

### Inverter Communication Instruction

#### ■ Inverter operation monitoring (Status check)

| Instruction symbol | Description                                                                                          | Reference |
|--------------------|------------------------------------------------------------------------------------------------------|-----------|
| IVCK               | Reads the contents of the corresponding instruction code from the specified inverter station number. | Page 1115 |

#### ■ Inverter operations control (Drive)

| Instruction symbol | Description                                                                                         | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------|-----------|
| IVDR               | Writes the contents of the corresponding instruction code to the specified inverter station number. | Page 1117 |

#### ■ Inverter parameter read

| Instruction symbol | Description                                                   | Reference |
|--------------------|---------------------------------------------------------------|-----------|
| IVRD               | Reads a parameter from the specified inverter station number. | Page 1119 |

#### ■ Inverter parameter write

| Instruction symbol | Description                                                  | Reference |
|--------------------|--------------------------------------------------------------|-----------|
| IVWR               | Writes a parameter to the specified inverter station number. | Page 1121 |

#### ■ Inverter parameter block write

| Instruction symbol | Description                                                                                      | Reference |
|--------------------|--------------------------------------------------------------------------------------------------|-----------|
| IVBWR              | Writes the range of the specified data tables to the specified inverter station number in batch. | Page 1123 |

#### ■ Inverter multi command

| Instruction symbol | Description                                                                                                    | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------|-----------|
| IVMC               | Sends/receives data corresponding to the send/receive data type to/from the specified inverter station number. | Page 1125 |

### MODBUS Communication Instruction

| Instruction symbol | Description                                                                                                                                                                                                                     | Reference |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| ADPRW              | Communicates (reads/writes data) with the Slave compatible with the MODBUS Master. This instruction is used when the master station has only one channel. (This instruction cannot be used with ADPRW [using eight operands].)  | Page 1127 |
|                    | Communicates (reads/writes data) with the Slave compatible with the MODBUS Master. This instruction can be used on master stations with up to four channels. (This instruction cannot be used with ADPRW [using six operands].) | Page 1129 |

### Predefined Protocol Support Function Instruction

| Instruction symbol | Description                                                                                         | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------|-----------|
| S.CPRTCL           | Executes the protocol specified by the communication protocol support tool of the engineering tool. | Page 1131 |
| SP.CPRTCL          |                                                                                                     |           |

## 4.7 Positioning Instruction

### Positioning instruction

#### ■Zero return(OPR) with 16-bit/32- bit data DOG search

| Instruction symbol | Description                                                                                                                                                                                                                                                                                                                                        | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| DSZR               | • When FX3 compatible operand is specified                                                                                                                                                                                                                                                                                                         | Page 1136 |
| DDSZR              | Specifies the proximity dog signal, zero signal and device (Y). Outputs a pulse with the specified device (Y) to perform the zero return operation.<br>• When FX5 operand is specified<br>Specifies the original position return speed, creep speed and axis number. Outputs a pulse with the specified axis to perform the zero return operation. | Page 1140 |

#### ■16-bit/32-bit data interrupt positioning

| Instruction symbol | Description                                                                                                                                                                                                                | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| DVIT               | • When FX3 compatible operand is specified                                                                                                                                                                                 | Page 1142 |
| DDVIT              | Performs interrupt positioning with the specified travel distance, speed, and device (Y).<br>• When FX5 operand is specified<br>Performs interrupt positioning with the specified travel distance, speed, and axis number. | Page 1146 |

#### ■Positioning by one table operation

| Instruction symbol | Description                                                                                                                                                                                                                                                                              | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| TBL                | • When FX3 compatible operand is specified<br>Outputs 1 table operation from the table set by the parameter as pulse with specified device (Y).<br>• When FX5 operand is specified<br>Outputs 1 table operation from the table set by the parameter as pulse with specified axis number. | Page 1150 |

#### ■Positioning by multiple table operation

| Instruction symbol | Description                                                                                                           | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|-----------|
| DRVTL              | Outputs continuous multiple table operations from the table set by the parameter as pulse with specified axis number. | Page 1152 |

#### ■Multiple axes concurrent drive positioning

| Instruction symbol | Description                                                                   | Reference |
|--------------------|-------------------------------------------------------------------------------|-----------|
| DRVMUL             | Outputs the table set by the parameter as pulse with specified multiple axes. | Page 1154 |

#### ■32-bit data ABS current value read

| Instruction symbol | Description                                              | Reference |
|--------------------|----------------------------------------------------------|-----------|
| DABS               | Reads the absolute position data of the servo amplifier. | Page 1156 |

#### ■16-bit/32-bit data variable speed pulse

| Instruction symbol | Description                                                                                                                                                                                                                              | Reference |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| PLSV               | • When FX3 compatible operand is specified                                                                                                                                                                                               | Page 1158 |
| DPLSV              | Specifies the command speed and output device (Y) and uses the specified device (Y) to perform pulse output.<br>• When FX5 operand is specified<br>Specifies the command speed and performs pulse output with the specified axis number. | Page 1162 |

#### ■16-bit/32-bit data relative positioning

| Instruction symbol | Description                                                                                                                                                                                                                                                                            | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| DRVI               | • When FX3 compatible operand is specified                                                                                                                                                                                                                                             | Page 1166 |
| DDRVI              | Specifies the travel distance from the current position, speed and performs pulse output with the specified device (Y).<br>• When FX5 operand is specified<br>Specifies the travel distance from the current position, speed and performs pulse output with the specified axis number. | Page 1170 |

## ■16-bit/32-bit data absolute positioning

| Instruction symbol | Description                                                                                                                                                                                                          | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| DRVA               | <ul style="list-style-type: none"> <li>When FX3 compatible operand is specified</li> </ul> Specifies the travel distance from the reference position, speed and performs pulse output with the specified device (Y). | Page 1174 |
| DDRVA              |                                                                                                                                                                                                                      | Page 1178 |
|                    | <ul style="list-style-type: none"> <li>When FX5 operand is specified</li> </ul> Specifies the travel distance from the reference position, speed and performs pulse output with the specified axis number.           |           |

## Positioning module

### ■Restoring the absolute position

| Instruction symbol | Description                                       | Reference |
|--------------------|---------------------------------------------------|-----------|
| G.ABRST1           | Restores the absolute position of specified axis. | Page 1182 |
| G.ABRST2           |                                                   |           |

### ■Starting the positioning

| Instruction symbol | Description                               | Reference |
|--------------------|-------------------------------------------|-----------|
| GP.PSTRT1          | Starts positioning of the specified axis. | Page 1186 |
| GP.PSTRT2          |                                           |           |

### ■Teaching

| Instruction symbol | Description                               | Reference |
|--------------------|-------------------------------------------|-----------|
| GP.TEACH1          | Performs teaching for the specified axis. | Page 1189 |
| GP.TEACH2          |                                           |           |

### ■Backing up module data (writing data to the flash ROM)

| Instruction symbol | Description                                                                             | Reference |
|--------------------|-----------------------------------------------------------------------------------------|-----------|
| GP.PFWRT           | Writes the positioning data and block start data in the buffer memory to the flash ROM. | Page 1192 |

### ■Initializing the module

| Instruction symbol | Description                                                      | Reference |
|--------------------|------------------------------------------------------------------|-----------|
| GP.PINIT           | Initializes the setting data in the buffer memory and flash ROM. | Page 1195 |

## 4.8 BFM Device Read/ Write Instruction

### Divided BFM Read

| Instruction symbol | Description                                                                                                                                               | Reference |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| RBFM               | Divides and reads data from the continuous buffer memory in the intelligent module.<br>(This instruction cannot be used with the FX5 intelligent module.) | Page 1198 |

### Divided BFM Write

| Instruction symbol | Description                                                                                                                                              | Reference |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| WBFM               | Divides and writes data to the continuous buffer memory in the intelligent module.<br>(This instruction cannot be used with the FX5 intelligent module.) | Page 1202 |

# 5 STANDARD FUNCTIONS/FUNCTION BLOCKS

## 5.1 Standard Functions

### Type conversion functions

#### Converting BOOL to WORD/DWORD

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| BOOL_TO_WORD    | Converts BOOL type data to WORD type data.  | Page 1206 |
| BOOL_TO_WORD_E  |                                             |           |
| BOOL_TO_DWORD   | Converts BOOL type data to DWORD type data. | Page 1208 |
| BOOL_TO_DWORD_E |                                             |           |

#### Converting BOOL to INT/DINT

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| BOOL_TO_INT     | Converts BOOL type data to INT type data.  | Page 1209 |
| BOOL_TO_INT_E   |                                            |           |
| BOOL_TO_DINT    | Converts BOOL type data to DINT type data. | Page 1210 |
| BOOL_TO_DINT_E  |                                            |           |

#### Converting BOOL to TIME

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| BOOL_TO_TIME    | Converts BOOL type data to TIME type data. | Page 1211 |
| BOOL_TO_TIME_E  |                                            |           |

#### Converting BOOL to STRING

| Function symbol  | Description                                  | Reference |
|------------------|----------------------------------------------|-----------|
| BOOL_TO_STRING   | Converts BOOL type data to STRING type data. | Page 1212 |
| BOOL_TO_STRING_E |                                              |           |

#### Converting WORD to BOOL

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| WORD_TO_BOOL    | Converts WORD type data to BOOL type data. | Page 1213 |
| WORD_TO_BOOL_E  |                                            |           |

#### Converting WORD to DWORD

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| WORD_TO_DWORD   | Converts WORD type data to DWORD type data. | Page 1214 |
| WORD_TO_DWORD_E |                                             |           |

#### Converting WORD to INT/DINT

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| WORD_TO_INT     | Converts WORD type data to INT type data.  | Page 1215 |
| WORD_TO_INT_E   |                                            |           |
| WORD_TO_DINT    | Converts WORD type data to DINT type data. | Page 1216 |
| WORD_TO_DINT_E  |                                            |           |

## Converting WORD to TIME

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| WORD_TO_TIME    | Converts WORD type data to TIME type data. | Page 1218 |
| WORD_TO_TIME_E  |                                            |           |

## Converting DWORD to BOOL

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| DWORD_TO_BOOL   | Converts DWORD type data to BOOL type data. | Page 1219 |
| DWORD_TO_BOOL_E |                                             |           |

## Converting DWORD to WORD

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| DWORD_TO_WORD   | Converts DWORD type data to WORD type data. | Page 1220 |
| DWORD_TO_WORD_E |                                             |           |

## Converting DWORD to INT/DINT

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| DWORD_TO_INT    | Converts DWORD type data to INT type data.  | Page 1222 |
| DWORD_TO_INT_E  |                                             |           |
| DWORD_TO_DINT   | Converts DWORD type data to DINT type data. | Page 1224 |
| DWORD_TO_DINT_E |                                             |           |

## Converting DWORD to TIME

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| DWORD_TO_TIME   | Converts DWORD type data to TIME type data. | Page 1225 |
| DWORD_TO_TIME_E |                                             |           |

## Converting INT to BOOL

| Function symbol | Description                               | Reference |
|-----------------|-------------------------------------------|-----------|
| INT_TO_BOOL     | Converts INT type data to BOOL type data. | Page 1226 |
| INT_TO_BOOL_E   |                                           |           |

## Converting INT to WORD/DWORD

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| INT_TO_WORD     | Converts INT type data to WORD type data.  | Page 1227 |
| INT_TO_WORD_E   |                                            |           |
| INT_TO_DWORD    | Converts INT type data to DWORD type data. | Page 1228 |
| INT_TO_DWORD_E  |                                            |           |

## Converting INT to DINT

| Function symbol | Description                               | Reference |
|-----------------|-------------------------------------------|-----------|
| INT_TO_DINT     | Converts INT type data to DINT type data. | Page 1230 |
| INT_TO_DINT_E   |                                           |           |

## Converting INT to BCD

| Function symbol | Description                              | Reference |
|-----------------|------------------------------------------|-----------|
| INT_TO_BCD      | Converts INT type data to BCD type data. | Page 1231 |
| INT_TO_BCD_E    |                                          |           |

## Converting INT to REAL

| Function symbol | Description                               | Reference |
|-----------------|-------------------------------------------|-----------|
| INT_TO_REAL     | Converts INT type data to REAL type data. | Page 1233 |
| INT_TO_REAL_E   |                                           |           |

## Converting INT to TIME

| Function symbol | Description                               | Reference |
|-----------------|-------------------------------------------|-----------|
| INT_TO_TIME     | Converts INT type data to TIME type data. | Page 1234 |
| INT_TO_TIME_E   |                                           |           |

## Converting INT to STRING

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| INT_TO_STRING   | Converts INT type data to STRING type data. | Page 1235 |
| INT_TO_STRING_E |                                             |           |

## Converting DINT to BOOL

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| DINT_TO_BOOL    | Converts DINT type data to BOOL type data. | Page 1237 |
| DINT_TO_BOOL_E  |                                            |           |

## Converting DINT to WORD/DWORD

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| DINT_TO_WORD    | Converts DINT type data to WORD type data.  | Page 1238 |
| DINT_TO_WORD_E  |                                             |           |
| DINT_TO_DWORD   | Converts DINT type data to DWORD type data. | Page 1240 |
| DINT_TO_DWORD_E |                                             |           |

## Converting DINT to INT

| Function symbol | Description                               | Reference |
|-----------------|-------------------------------------------|-----------|
| DINT_TO_INT     | Converts DINT type data to INT type data. | Page 1241 |
| DINT_TO_INT_E   |                                           |           |

## Converting DINT to BCD

| Function symbol | Description                               | Reference |
|-----------------|-------------------------------------------|-----------|
| DINT_TO_BCD     | Converts DINT type data to BCD type data. | Page 1243 |
| DINT_TO_BCD_E   |                                           |           |

## Converting DINT to REAL

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| DINT_TO_REAL    | Converts DINT type data to REAL type data. | Page 1245 |
| DINT_TO_REAL_E  |                                            |           |

## Converting DINT to TIME

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| DINT_TO_TIME    | Converts DINT type data to TIME type data. | Page 1246 |
| DINT_TO_TIME_E  |                                            |           |

## Converting DINT to STRING

| Function symbol  | Description                                  | Reference |
|------------------|----------------------------------------------|-----------|
| DINT_TO_STRING   | Converts DINT type data to STRING type data. | Page 1247 |
| DINT_TO_STRING_E |                                              |           |

## Converting BCD to INT/DINT

| Function symbol | Description                               | Reference |
|-----------------|-------------------------------------------|-----------|
| BCD_TO_INT      | Converts BCD type data to INT type data.  | Page 1249 |
| BCD_TO_INT_E    |                                           |           |
| BCD_TO_DINT     | Converts BCD type data to DINT type data. | Page 1251 |
| BCD_TO_DINT_E   |                                           |           |

## Converting REAL to INT/DINT

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| REAL_TO_INT     | Converts REAL type data to INT type data.  | Page 1253 |
| REAL_TO_INT_E   |                                            |           |
| REAL_TO_DINT    | Converts REAL type data to DINT type data. | Page 1255 |
| REAL_TO_DINT_E  |                                            |           |

## Converting REAL to STRING

| Function symbol  | Description                                                    | Reference |
|------------------|----------------------------------------------------------------|-----------|
| REAL_TO_STRING   | Converts REAL type data to STRING type data (exponent format). | Page 1257 |
| REAL_TO_STRING_E |                                                                |           |

## Converting TIME to BOOL

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| TIME_TO_BOOL    | Converts TIME type data to BOOL type data. | Page 1260 |
| TIME_TO_BOOL_E  |                                            |           |

## Converting TIME to WORD/DWORD

| Function symbol | Description                                 | Reference |
|-----------------|---------------------------------------------|-----------|
| TIME_TO_WORD    | Converts TIME type data to WORD type data.  | Page 1261 |
| TIME_TO_WORD_E  |                                             |           |
| TIME_TO_DWORD   | Converts TIME type data to DWORD type data. | Page 1262 |
| TIME_TO_DWORD_E |                                             |           |

## Converting TIME to INT/DINT

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| TIME_TO_INT     | Converts TIME type data to INT type data.  | Page 1263 |
| TIME_TO_INT_E   |                                            |           |
| TIME_TO_DINT    | Converts TIME type data to DINT type data. | Page 1264 |
| TIME_TO_DINT_E  |                                            |           |

## Converting TIME to STRING

| Function symbol  | Description                                  | Reference |
|------------------|----------------------------------------------|-----------|
| TIME_TO_STRING   | Converts TIME type data to STRING type data. | Page 1265 |
| TIME_TO_STRING_E |                                              |           |

## Converting STRING to BOOL

| Function symbol  | Description                                  | Reference |
|------------------|----------------------------------------------|-----------|
| STRING_TO_BOOL   | Converts STRING type data to BOOL type data. | Page 1267 |
| STRING_TO_BOOL_E |                                              |           |

## Converting STRING to INT/DINT

| Function symbol  | Description                                  | Reference |
|------------------|----------------------------------------------|-----------|
| STRING_TO_INT    | Converts STRING type data to INT type data.  | Page 1268 |
| STRING_TO_INT_E  |                                              |           |
| STRING_TO_DINT   | Converts STRING type data to DINT type data. | Page 1270 |
| STRING_TO_DINT_E |                                              |           |

## Converting STRING to REAL

| Function symbol  | Description                                  | Reference |
|------------------|----------------------------------------------|-----------|
| STRING_TO_REAL   | Converts STRING type data to REAL type data. | Page 1272 |
| STRING_TO_REAL_E |                                              |           |

## Converting STRING to TIME

| Function symbol  | Description                                  | Reference |
|------------------|----------------------------------------------|-----------|
| STRING_TO_TIME   | Converts STRING type data to TIME type data. | Page 1275 |
| STRING_TO_TIME_E |                                              |           |

## Converting bit array to INT/DINT

| Function symbol  | Description                                                            | Reference |
|------------------|------------------------------------------------------------------------|-----------|
| BITARR_TO_INT    | Converts a bit array to INT type data for a specified number of bits.  | Page 1276 |
| BITARR_TO_INT_E  |                                                                        |           |
| BITARR_TO_DINT   | Converts a bit array to DINT type data for a specified number of bits. | Page 1277 |
| BITARR_TO_DINT_E |                                                                        |           |

## Converting INT/DINT to bit array

| Function symbol  | Description                                                  | Reference |
|------------------|--------------------------------------------------------------|-----------|
| INT_TO_BITARR    | Outputs low-order (n) bits of INT type data to a bit array.  | Page 1278 |
| INT_TO_BITARR_E  |                                                              |           |
| DINT_TO_BITARR   | Outputs low-order (n) bits of DINT type data to a bit array. | Page 1279 |
| DINT_TO_BITARR_E |                                                              |           |

## Bit array copy

| Function symbol | Description                                     | Reference |
|-----------------|-------------------------------------------------|-----------|
| CPY_BITARR      | Copies specified number of bits of a bit array. | Page 1280 |
| CPY_BITARR_E    |                                                 |           |

## Reading the specified bit of word label

| Function symbol  | Description                                        | Reference |
|------------------|----------------------------------------------------|-----------|
| GET_BIT_OF_INT   | Reads a value of a specified bit of INT type data. | Page 1281 |
| GET_BIT_OF_INT_E |                                                    |           |

## Writing the specified bit of word label

| Function symbol  | Description                                         | Reference |
|------------------|-----------------------------------------------------|-----------|
| SET_BIT_OF_INT   | Writes a value to a specified bit of INT type data. | Page 1282 |
| SET_BIT_OF_INT_E |                                                     |           |

## Copying the specified bit of word label

| Function symbol  | Description                                                                          | Reference |
|------------------|--------------------------------------------------------------------------------------|-----------|
| CPY_BIT_OF_INT   | Copies a specified bit of INT type data to a specified bit of another INT type data. | Page 1283 |
| CPY_BIT_OF_INT_E |                                                                                      |           |

## Unnecessary of type conversion

| Function symbol | Description                            | Reference |
|-----------------|----------------------------------------|-----------|
| GET_BOOL_ADDR   | Converts a data type to the BOOL type. | Page 1284 |
| GET_INT_ADDR    | Converts a data type to the INT type.  |           |
| GET_WORD_ADDR   | Converts a data type to the WORD type. |           |

## Standard functions of one numeric variable

### Absolute value

| Function symbol | Description                                   | Reference |
|-----------------|-----------------------------------------------|-----------|
| ABS             | Outputs the absolute value of an input value. | Page 1285 |
| ABS_E           |                                               |           |

### Square root

| Function symbol | Description                                | Reference |
|-----------------|--------------------------------------------|-----------|
| SQRT            | Outputs the square root of an input value. | Page 1287 |
| SQRT_E          |                                            |           |

### Natural logarithm operation

| Function symbol | Description                                                       | Reference |
|-----------------|-------------------------------------------------------------------|-----------|
| LN              | Outputs the natural logarithm operation result of an input value. | Page 1288 |
| LN_E            |                                                                   |           |

### Calculating the common logarithm

| Function symbol | Description                                                                                              | Reference |
|-----------------|----------------------------------------------------------------------------------------------------------|-----------|
| LOG             | Outputs the operation result of the common logarithm (the logarithm whose base is 10) of an input value. | Page 1289 |
| LOG_E           |                                                                                                          |           |

### Exponential operation

| Function symbol | Description                                                 | Reference |
|-----------------|-------------------------------------------------------------|-----------|
| EXP             | Outputs the exponential operation result of an input value. | Page 1291 |
| EXP_E           |                                                             |           |

## Sine operation

| Function symbol | Description                                      | Reference |
|-----------------|--------------------------------------------------|-----------|
| SIN             | Outputs the sine of the angle of an input value. | Page 1292 |
| SIN_E           |                                                  |           |

## Cosine operation

| Function symbol | Description                                        | Reference |
|-----------------|----------------------------------------------------|-----------|
| COS             | Outputs the cosine of the angle of an input value. | Page 1293 |
| COS_E           |                                                    |           |

## Tangent operation

| Function symbol | Description                                               | Reference |
|-----------------|-----------------------------------------------------------|-----------|
| TAN             | Outputs the tangent of the angle value of an input value. | Page 1294 |
| TAN_E           |                                                           |           |

## Arc sine operation

| Function symbol | Description                                   | Reference |
|-----------------|-----------------------------------------------|-----------|
| ASIN            | Outputs the arc sine value of an input value. | Page 1296 |
| ASIN_E          |                                               |           |

## Arc cosine operation

| Function symbol | Description                                     | Reference |
|-----------------|-------------------------------------------------|-----------|
| ACOS            | Outputs the arc cosine value of an input value. | Page 1298 |
| ACOS_E          |                                                 |           |

## Arc tangent operation

| Function symbol | Description                                      | Reference |
|-----------------|--------------------------------------------------|-----------|
| ATAN            | Outputs the arc tangent value of an input value. | Page 1300 |
| ATAN_E          |                                                  |           |

## Standard arithmetic functions

### Addition

| Function symbol | Description                                                       | Reference |
|-----------------|-------------------------------------------------------------------|-----------|
| ADD             | Outputs the sum of input values $((s1) + (s2) + \dots + (s28))$ . | Page 1302 |
| ADD_E           |                                                                   |           |

### Multiplication

| Function symbol | Description                                                                          | Reference |
|-----------------|--------------------------------------------------------------------------------------|-----------|
| MUL             | Outputs the product of input values $((s1) \times (s2) \times \dots \times (s28))$ . | Page 1304 |
| MUL_E           |                                                                                      |           |

### Subtraction

| Function symbol | Description                                              | Reference |
|-----------------|----------------------------------------------------------|-----------|
| SUB             | Outputs the difference of input values $((s1) - (s2))$ . | Page 1306 |
| SUB_E           |                                                          |           |

## Division

| Function symbol | Description                                               | Reference |
|-----------------|-----------------------------------------------------------|-----------|
| DIV             | Outputs the quotient of input values $((s1) \div (s2))$ . | Page 1308 |
| DIV_E           |                                                           |           |

## Remainder

| Function symbol | Description                                                | Reference |
|-----------------|------------------------------------------------------------|-----------|
| MOD             | Outputs the remainder of input values $((s1) \div (s2))$ . | Page 1310 |
| MOD_E           |                                                            |           |

## Exponentiation

| Function symbol | Description                                   | Reference |
|-----------------|-----------------------------------------------|-----------|
| EXPT            | Outputs the exponentiation of an input value. | Page 1312 |
| EXPT_E          |                                               |           |

## Move operation

| Function symbol | Description                    | Reference |
|-----------------|--------------------------------|-----------|
| MOVE            | Assigns an input value to (d). | Page 1314 |
| MOVE_E          |                                |           |

## Standard bit shift functions

### Shifting n-bit data to left/right

| Function symbol | Description                                                         | Reference |
|-----------------|---------------------------------------------------------------------|-----------|
| SHL             | Shifts an input value leftward by (n) bits and outputs the result.  | Page 1316 |
| SHL_E           |                                                                     |           |
| SHR             | Shifts an input value rightward by (n) bits and outputs the result. | Page 1318 |
| SHR_E           |                                                                     |           |

### Rotating n-bit data to left/right

| Function symbol | Description                                                          | Reference |
|-----------------|----------------------------------------------------------------------|-----------|
| ROL             | Rotates an input value leftward by (n) bits and outputs the result.  | Page 1320 |
| ROL_E           |                                                                      |           |
| ROR             | Rotates an input value rightward by (n) bits and outputs the result. | Page 1322 |
| ROR_E           |                                                                      |           |

## Standard bitwise boolean functions

### AND operation, OR operation, XOR operation, NOT operation

| Function symbol | Description                                        | Reference |
|-----------------|----------------------------------------------------|-----------|
| AND             | Outputs the logical product of input values.       | Page 1324 |
| AND_E           |                                                    |           |
| OR              | Outputs the logical sum of input values.           |           |
| OR_E            |                                                    |           |
| XOR             | Outputs the exclusive logical sum of input values. |           |
| XOR_E           |                                                    |           |
| NOT             | Outputs the logical negation of input values.      | Page 1326 |
| NOT_E           |                                                    |           |

## Standard selection functions

### Selection

| Function symbol | Description                     | Reference |
|-----------------|---------------------------------|-----------|
| SEL             | Outputs a selected input value. | Page 1327 |
| SEL_E           |                                 |           |

### Selecting Maximum/Minimum Value

| Function symbol | Description                                  | Reference |
|-----------------|----------------------------------------------|-----------|
| MAX             | Outputs the maximum value of an input value. | Page 1329 |
| MAX_E           |                                              |           |
| MIN             | Outputs the minimum value of an input value. |           |
| MIN_E           |                                              |           |

### Limit Control

| Function symbol | Description                                                        | Reference |
|-----------------|--------------------------------------------------------------------|-----------|
| LIMIT           | Outputs an input value controlled with the upper and lower limits. | Page 1331 |
| LIMIT_E         |                                                                    |           |

### Multiplexer

| Function symbol | Description                           | Reference |
|-----------------|---------------------------------------|-----------|
| MUX             | Outputs one of multiple input values. | Page 1333 |
| MUX_E           |                                       |           |

## Standard comparison functions

### Compare

| Function symbol | Description                                         | Reference |
|-----------------|-----------------------------------------------------|-----------|
| GT              | Outputs the data comparison result of input values. | Page 1335 |
| GT_E            |                                                     |           |
| GE              |                                                     |           |
| GE_E            |                                                     |           |
| EQ              |                                                     |           |
| EQ_E            |                                                     |           |
| LE              |                                                     |           |
| LE_E            |                                                     |           |
| LT              |                                                     |           |
| LT_E            |                                                     |           |
| NE              |                                                     | Page 1337 |
| NE_E            |                                                     |           |

# Standard character string functions

## Character string length detection

| Function symbol | Description                                                             | Reference |
|-----------------|-------------------------------------------------------------------------|-----------|
| LEN             | Detects the length of an input character string and outputs the result. | Page 1339 |
| LEN_E           |                                                                         |           |

## Extracting character string data from the left/right

| Function symbol | Description                                                                           | Reference |
|-----------------|---------------------------------------------------------------------------------------|-----------|
| LEFT            | Outputs specified number of characters from the left of input character string data.  | Page 1341 |
| LEFT_E          |                                                                                       |           |
| RIGHT           | Outputs specified number of characters from the right of input character string data. |           |
| RIGHT_E         |                                                                                       |           |

## Extract mid string

| Function symbol | Description                                                                                     | Reference |
|-----------------|-------------------------------------------------------------------------------------------------|-----------|
| MID             | Outputs specified number of characters from an arbitrary position of an input character string. | Page 1343 |
| MID_E           |                                                                                                 |           |

## String concatenation

| Function symbol | Description                                           | Reference |
|-----------------|-------------------------------------------------------|-----------|
| CONCAT          | Concatenates character strings and output the result. | Page 1345 |
| CONCAT_E        |                                                       |           |

## Inserting character string

| Function symbol | Description                                                                     | Reference |
|-----------------|---------------------------------------------------------------------------------|-----------|
| INSERT          | Inserts a character string into another character string and output the result. | Page 1347 |
| INSERT_E        |                                                                                 |           |

## Deleting character string

| Function symbol | Description                                                              | Reference |
|-----------------|--------------------------------------------------------------------------|-----------|
| DELETE          | Deletes an arbitrary range of a character string and outputs the result. | Page 1349 |
| DELETE_E        |                                                                          |           |

## Replacing character string

| Function symbol | Description                                                               | Reference |
|-----------------|---------------------------------------------------------------------------|-----------|
| REPLACE         | Replaces an arbitrary range of a character string and outputs the result. | Page 1351 |
| REPLACE_E       |                                                                           |           |

## Searching character string

| Function symbol | Description                                             | Reference |
|-----------------|---------------------------------------------------------|-----------|
| FIND            | Searches for a character string and outputs the result. | Page 1354 |
| FIND_E          |                                                         |           |

## Time data functions

### Addition

| Function symbol | Description                                                   | Reference |
|-----------------|---------------------------------------------------------------|-----------|
| ADD_TIME        | Outputs the sum of input values (time data) $((s1) + (s2))$ . | Page 1356 |
| ADD_TIME_E      |                                                               |           |

### Subtraction

| Function symbol | Description                                                          | Reference |
|-----------------|----------------------------------------------------------------------|-----------|
| SUB_TIME        | Outputs the difference of input values (time data) $((s1) - (s2))$ . | Page 1358 |
| SUB_TIME_E      |                                                                      |           |

### Multiplication

| Function symbol | Description                                                            | Reference |
|-----------------|------------------------------------------------------------------------|-----------|
| MUL_TIME        | Outputs the product of input values (time data) $((s1) \times (s2))$ . | Page 1360 |
| MUL_TIME_E      |                                                                        |           |

### Division

| Function symbol | Description                                                           | Reference |
|-----------------|-----------------------------------------------------------------------|-----------|
| DIV_TIME        | Outputs the quotient of input values (time data) $((s1) \div (s2))$ . | Page 1362 |
| DIV_TIME_E      |                                                                       |           |

## 5.2 Standard Function Blocks

### Bistable function blocks

#### Bistable function blocks (set priority)

| Function block symbol | Description                                                               | Reference |
|-----------------------|---------------------------------------------------------------------------|-----------|
| SR                    | Judges two input values and outputs 1 (TRUE) or 0 (FALSE). (Set priority) | Page 1366 |
| SR_E                  |                                                                           |           |

#### Bistable function blocks (reset priority)

| Function block symbol | Description                                                                 | Reference |
|-----------------------|-----------------------------------------------------------------------------|-----------|
| RS                    | Judges two input values and outputs 1 (TRUE) or 0 (FALSE). (Reset priority) | Page 1368 |
| RS_E                  |                                                                             |           |

### Edge detection function blocks

#### Rising edge detector

| Function block symbol | Description                                                      | Reference |
|-----------------------|------------------------------------------------------------------|-----------|
| R_TRIG                | Detects the rising edge of a signal, and outputs a pulse signal. | Page 1370 |
| R_TRIG_E              |                                                                  |           |

#### Falling edge detector

| Function block symbol | Description                                                       | Reference |
|-----------------------|-------------------------------------------------------------------|-----------|
| F_TRIG                | Detects the falling edge of a signal, and outputs a pulse signal. | Page 1372 |
| F_TRIG_E              |                                                                   |           |

### Counter function blocks

#### Up counter

| Function block symbol | Description                                          | Reference |
|-----------------------|------------------------------------------------------|-----------|
| CTU                   | Counts up the number of times of rising of a signal. | Page 1374 |
| CTU_E                 |                                                      |           |

#### Down counter

| Function block symbol | Description                                            | Reference |
|-----------------------|--------------------------------------------------------|-----------|
| CTD                   | Counts down the number of times of rising of a signal. | Page 1376 |
| CTD_E                 |                                                        |           |

#### Up/Down counter

| Function block symbol | Description                                               | Reference |
|-----------------------|-----------------------------------------------------------|-----------|
| CTUD                  | Counts up/down the number of times of rising of a signal. | Page 1378 |
| CTUD_E                |                                                           |           |

#### Counter function block

| Function block symbol | Description                                                            | Reference |
|-----------------------|------------------------------------------------------------------------|-----------|
| COUNTER_FB_M          | Counts up the number of times of rising of a signal from (s3) to (s2). | Page 1381 |

## Timer function blocks

### Pulse timer

| Function block symbol | Description                               | Reference |
|-----------------------|-------------------------------------------|-----------|
| TP                    | Keeps ON a signal for specified duration. | Page 1383 |
| TP_E                  |                                           |           |
| TP_10                 |                                           |           |
| TP_10_E               |                                           |           |

### On-delay timer

| Function block symbol | Description                               | Reference |
|-----------------------|-------------------------------------------|-----------|
| TON                   | Turns ON a signal after a specified time. | Page 1385 |
| TON_E                 |                                           |           |
| TON_10                |                                           |           |
| TON_10_E              |                                           |           |

### Off-delay timer

| Function block symbol | Description                                | Reference |
|-----------------------|--------------------------------------------|-----------|
| TOF                   | Turns OFF a signal after a specified time. | Page 1387 |
| TOF_E                 |                                            |           |
| TOF_10                |                                            |           |
| TOF_10_E              |                                            |           |

### Timer function blocks

| Function block symbol | Description                                                                                               | Reference |
|-----------------------|-----------------------------------------------------------------------------------------------------------|-----------|
| TIMER_1_FB_M          | When the execution condition is established, these function blocks start the timer count to the set time. | Page 1389 |
| TIMER_10_FB_M         |                                                                                                           |           |
| TIMER_100_FB_M        |                                                                                                           |           |
| TIMER_CONT_FB_M       |                                                                                                           |           |
| TIMER_CONTHS_FB_M     |                                                                                                           |           |

# 6 SEQUENCE INSTRUCTIONS

## 6.1 Contact Instructions

### Operation start, series connection, parallel connection

#### LD, LDI, AND, ANI, OR, ORI

**FX5S****FX5UJ****FX5U****FX5UC**

- LD: NO contact operation start instruction/LDI: NC contact operation start instruction

These instructions capture the ON/OFF information of the device specified by (s), and use that as the operation result.

- AND: NO contact series connection instruction/ANI: NC contact series connection instruction

These instructions capture the ON/OFF information of the device specified by (s), AND with the operation result so far, and use the result as the operation result.

- OR: NO contact parallel connection instruction/ORI: NC contact parallel instruction

These instructions capture the ON/OFF information of the device specified by (s), OR with the operation result so far, and use the result as the operation result.

| Ladder diagram                                                                     | Structured text                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | <p>This becomes a assignment statement, operator, control syntax, etc.<br/>In the ST language, there are sometimes no instructions (symbols) that directly correspond to contacts such as LD, AND, and OR.<br/>When programming using assignment statements, express as shown in the following example.<br/>Example<br/>Y1:=(X0 OR X1) AND X2 AND NOT X3;<br/>Y2:=NOT X4 OR NOT X5;</p> |

#### FBD/LD

In the FBD/LD language, contact is used as well as the Ladder diagram.

#### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Remarks                  | Range | Data type | Data type (label) |
|---------|--------------------------|-------|-----------|-------------------|
| (s)     | Device used as a contact | —     | Bit       | ANY_BOOL          |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (DX) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |             |
| (s)     | ○                           | ○                         | ○     | — | ○           | —  | —                      | —        | — | —  | ○           |

## Processing details

### ■LD, LDI

- The LD instruction is the NO contact operation start instruction, and the LDI instruction is the NC contact operation start instruction. These instructions capture the ON/OFF information<sup>\*1</sup> of the specified device, and use the result as the operation result.

<sup>\*1</sup> When bits of word devices are specified, devices turn ON/OFF by the 1/0 status of the specified bit.

**Ex.**

- LD instruction (NO contact operation start)

Timing chart

- LDI instruction (NC contact operation start)

Timing chart

### ■AND, ANI

- The AND instruction is NO contact series connection instruction and the ANI instruction is NC contact series connection instruction. These instructions capture the ON/OFF information<sup>\*1</sup> of the specified bit device, AND with the operation result so far, and use the result as the operation result.

<sup>\*1</sup> When bits of word devices are specified, devices turn ON/OFF by the 1/0 status of the specified bit.

- There is no limitation to the number of series contacts. Any number of contacts can use this instructions consecutively.
- Output to other coils through contacts after the OUT instruction is called cascade output, and these outputs can be repeated any number of times as long as their order is correct.

**Ex.**

- AND instruction  
(series connection of NO contacts)

Timing chart

- ANI instruction  
(series connection of NC contacts)

Timing chart

## ■OR, ORI

- The OR instruction is NO contact parallel connection and the ORI instruction is NC contact parallel connection. These instructions capture the ON/OFF information<sup>\*1</sup> of the specified device, OR with the operation result so far, and use the result as the operation result.

<sup>\*1</sup> When bits of word devices are specified, devices turn ON/OFF by the 1/0 status of the specified bit.

- These instructions are connected in parallel from the step with this instruction to the previous step with the LD and LDI instruction.
- There is no limitation in the number of parallel connections.

### Point

- When bits of word devices are specified, bits are specified in hexadecimal. (For example, b11 of D0 is specified by "D0.B".)

### Ex.

- OR instruction  
(parallel connection of NO contacts)

Timing chart

- ORI instruction  
(parallel connection of NC contacts)

Timing chart

### Operation error

There is no operation error.

# Pulse operation start, pulse series connection, pulse parallel connection

## LDP, LDF, ANDP, ANDF, ORP, ORF

FX5S FX5UJ FX5U FX5UC

- LDP: Rising edge pulse operation start instruction  
This becomes conductive (ON) only at the rising edge (OFF to ON) of the bit device specified by (s).
- LDF: Falling edge pulse operation start instruction  
This becomes conductive (ON) only at the falling edge (ON to OFF) of the bit device specified by (s).
- ANDP: Rising edge pulse series connection instruction/ANDF: Falling edge pulse series connection instruction  
This instruction ANDs the bit device specified by (s) with the operation result so far, and uses the result as the operation result.
- ORP: Rising edge pulse parallel connection/ORF: Falling edge pulse parallel connection  
This instruction ORs the bit device specified by (s) with the operation result so far, and uses the result as the operation result.

| Ladder diagram | Structured text                                                                                              |

## Processing details

### ■LDP, LDF

- The LDP instruction is the rising edge pulse operation start instruction, and becomes conductive (ON) only at the rising edge (OFF to ON) of the specified bit device. When word devices are specified by bits, this instruction becomes conductive (ON) only when the status of the specified bit changes to 0→1. When only the LDP instruction is programmed, operation is the same as the conversion of the instruction under execution to pulse instruction (□P).

The following figure shows an example when a ladder using the LDP instruction is replaced with a ladder not using the LDP instruction.

- The LDF instruction is the falling edge pulse operation start instruction, and becomes conductive (ON) at the falling edge (ON to OFF) of the specified bit device. When word devices are specified by bits, this instruction becomes conductive only when the status of the specified bit changes to 1→0.

### ■ANDP, ANDF

- The ANDP instruction is the rising edge pulse series connection instruction, and the ANDF instruction is the falling edge pulse series connection. These instructions AND with the operation result so far, and uses the result as the operation result. The table below shows the ON/OFF information used by these instructions.

| Device specified by ANDP, ANDF |                                  | ANDP status | ANDF status |
|--------------------------------|----------------------------------|-------------|-------------|
| Bit device                     | Bit specification of word device |             |             |
| OFF to ON                      | 0→1                              | ON          | OFF         |
| OFF                            | 0                                | OFF         | OFF         |
| ON                             | 1                                | OFF         | OFF         |
| ON to OFF                      | 1→0                              | OFF         | ON          |

**Ex.**

- ANDP instruction (series connection of rising edge pulse)

Timing chart

- ANDF instruction (series connection of falling edge pulse)

Timing chart

## ■ ORP, ORF

- The ORP instruction is the rising edge pulse parallel connection instruction, and the ORF instruction is the falling edge pulse parallel connection instruction. These instructions OR with the operation result so far, and use the result as the operation result. The table below shows the ON/OFF information used by these instructions.

| Device specified by ORP, ORF |                                  | ORP status | ORF status |
|------------------------------|----------------------------------|------------|------------|
| Bit device                   | Bit specification of word device |            |            |
| OFF to ON                    | 0→1                              | ON         | OFF        |
| OFF                          | 0                                | OFF        | OFF        |
| ON                           | 1                                | OFF        | OFF        |
| ON to OFF                    | 1→0                              | OFF        | ON         |

## Program example

- LDP and ORP instructions (initial logical operation of rising edge pulse, and parallel connection of rising edge pulse)

Timing chart

In the example shown above, M0 is ON during only one operation cycle when X0 or X1 turn from OFF to ON.

- LDF and ORF instructions (initial logical operation of falling edge pulse, and parallel connection of falling edge pulse)

Timing chart

In the example shown above, M0 is ON during only one operation cycle when X0 or X1 turn from ON to OFF.

## Operation error

There is no operation error.

# Pulse NOT operation start, pulse NOT series connection, pulse NOT parallel connection

## LDPI, LDFI, ANDPI, ANDFI, ORPI, ORFI

FX5S    FX5UJ    FX5U    FX5UC

- LDPI: Rising edge pulse NOT operation start instruction  
This instruction becomes conductive (ON) at OFF, ON and the falling edge (ON to OFF) of the bit device specified by (s).
- LDFI: Falling edge pulse NOT operation start instruction  
This instruction becomes conductive (ON) at the rising edge (OFF to ON), OFF and ON of the bit device specified by (s).
- ANDPI: Rising edge pulse NOT series connection instruction/ANDFI: Falling edge pulse NOT series connection instruction  
This instruction ANDs the bit devices specified by (s) with the operation result so far, and uses the result as the operation result.
- ORPI: Rising edge pulse NOT parallel connection instruction/ORFI: Falling edge pulse NOT parallel connection instruction  
This instruction ORs the bit devices specified by (s) with the operation result so far, and uses the result as the operation result.

## Processing details

### ■LDPI, LDFI

- The LDPI instruction is the rising edge pulse NOT operation start instruction, and becomes conductive (ON) at OFF, ON and the falling edge (ON to OFF) of the specified bit device. When word devices are specified by bits, this instruction becomes conductive when the status of the specified bit is 0, 1, and when it changes 1→0.
- The LDFI instruction is the falling edge pulse NOT operation start instruction, and becomes conductive (ON) at the rising edge (OFF to ON), OFF and ON of the specified bit device. When word devices are specified by bits, this instruction becomes conductive (ON) when the status of the specified bit is 0, 1, and when it changes 0→1. The table below shows the ON/OFF information used by these instructions.

| Device specified by LDPI, LDFI |                                  | LDPI status | LDFI status |
|--------------------------------|----------------------------------|-------------|-------------|
| Bit device                     | Bit specification of word device |             |             |
| OFF to ON                      | 0→1                              | OFF         | ON          |
| OFF                            | 0                                | ON          | ON          |
| ON                             | 1                                | ON          | ON          |
| ON to OFF                      | 1→0                              | ON          | OFF         |

### ■ANDPI, ANDFI

- The ANDPI instruction is the rising edge pulse NOT series connection instruction, and the ANDFI instruction is the falling edge pulse NOT series connection instruction. These instructions AND with the operation result so far, and use the result as the operation result. The table below shows the ON/OFF information used by these instructions.

| Device specified by ANDPI, ANDFI |                                  | ANDPI status | ANDFI status |
|----------------------------------|----------------------------------|--------------|--------------|
| Bit device                       | Bit specification of word device |              |              |
| OFF to ON                        | 0→1                              | OFF          | ON           |
| OFF                              | 0                                | ON           | ON           |
| ON                               | 1                                | ON           | ON           |
| ON to OFF                        | 1→0                              | ON           | OFF          |

### ■ORPI, ORFI

- The ORPI instruction is the rising edge pulse NOT parallel connection instruction, and the ORFI instruction is the falling edge pulse NOT parallel connection instruction. These instructions OR with the operation result so far, and use the result as the operation result. The table below shows the ON/OFF information used by these instructions.

| Device specified by ORPI, ORFI |                                  | ORPI status | ORFI status |
|--------------------------------|----------------------------------|-------------|-------------|
| Bit device                     | Bit specification of word device |             |             |
| OFF to ON                      | 0→1                              | OFF         | ON          |
| OFF                            | 0                                | ON          | ON          |
| ON                             | 1                                | ON          | ON          |
| ON to OFF                      | 1→0                              | ON          | OFF         |

## Operation error

There is no operation error.

# 6.2 Association Instruction

## Ladder block series/parallel connection

### ANB, ORB

FX5S FX5UJ FX5U FX5UC

These instructions AND or OR the A and B blocks, and use the result as the operation result.

| Ladder diagram                                                                                                     | Structured text |
|--------------------------------------------------------------------------------------------------------------------|-----------------|
|  <p>A: A block<br/>B: B block</p> | Not supported.  |
| FBD/LD                                                                                                             | Not supported.  |

### Processing details

#### ■ANB

- This instruction ANDs the A and B blocks, and uses the result as the operation result.
- The symbol of this instruction is not NO contact symbol but a connection symbol.

Ex.

ANB instruction (series connection of ladder block)

## ■ ORB

- This instruction ORs the A and B blocks, and uses the result as the operation result.
- This instruction connects the ladder blocks of two contacts or more in parallel. For parallel connection of only one contact, use the OR and ORI instructions; there is no need to use this instruction.
- The symbol of this instruction is not NO contact symbol but a connection symbol.

### Point

- The number of parallel circuits that can be connected by the ORB instruction is not limited. (when the recommended program is used)
- The ORB instruction can be used by one operation. However, note that the LD instruction and the LDI instruction can repeatedly be used 8 times or less. (when the recommended program is not used)

Circuit program

List program

Appropriate program

```
0 LD X0
1 AND X1
2 LD X2
3 AND X3
4 ORB
5 LDI X4
6 AND X5
7 ORB
8 OUT Y6
```

Inappropriate program

```
0 LD X0
1 AND X1
2 LD X2
3 AND X3
4 LDI X4
5 AND X5
6 ORB
7 ORB
8 OUT Y6
```

## Operation error

There is no operation error.

# Storing/reading/clearing the operation result

## MPS, MRD, MPP

FX5S    FX5UJ    FX5U    FX5UC

- MPS: This instruction stores the preceding operation result (ON/OFF) to memory.
- MRD, MPP: These instructions read the operation result stored by the MPS instruction, and executes operations from the next step using that operation result.

| Ladder diagram                                                                    | Structured text                                 |
|-----------------------------------------------------------------------------------|-------------------------------------------------|
|  | ENO:=MPS(EN);<br>ENO:=MRD(EN);<br>ENO:=MPP(EN); |

### FBD/LD

6

## Processing details

### ■MPS

- This instruction stores the preceding operation result (ON/OFF) to memory.
- This instruction can be used up to 16 times consecutively. When MPP instruction is used in between, the number of uses of MPS instruction is decremented by 1.

### ■MRD

- This instruction reads the operation result stored by the MPS instruction to memory, and executes operations from the next step using that operation result.

### ■MPP

- This instruction reads the operation result stored by the MPS instruction to memory, and executes operations from the next step using that operation result.
- This instruction clears the operation result stored by the MPS instruction from memory.
- The number of uses of MPS instruction is decremented by 1.

Ex.

## Program example

- Continuous use of MPS instruction - once  
Only one stack is used in this example.

- Continuous use of MPS instruction - once (both ANB and ORB used)

- Continuous use of MPS instruction - twice

- Continuous use of MPS instruction - four times

MPS instruction is used three times in programming.

By changing the circuit as follows, the same contents can be programmed easily without MPS instruction.

### Operation error

There is no operation error.

# Inverting the operation result

## INV

FX5S    FX5UJ    FX5U    FX5UC

This instruction inverts the operation result up to this instruction.

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=INV(EN);   |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Processing details

- This instruction inverts the operation result up to this instruction.

| Operation result up to the INV instruction | Operation result after execution of INV instruction |
|--------------------------------------------|-----------------------------------------------------|
| OFF                                        | ON                                                  |
| ON                                         | OFF                                                 |

### Operation error

There is no operation error.

**Point**

- This instruction operates using the operation result so far. Hence, use it at the same position as the AND instruction. This instruction cannot be used at positions where the LD and OR instructions are programmed.
- If a ladder block is used, the operation result is inverted within the range of the ladder block. When operating a ladder with this instruction and the ANB instruction, pay attention to the inversion range.

( ) : Inversion range

For details ANB instruction, refer to the following.

 Page 123 ANB, ORB

# Converting the operation result into a pulse

## MEP, MEF

FX5S    FX5UJ    FX5U    FX5UC

- MEP: This instruction turns ON at the rising edge of the operation result up to the MEP instruction and turns OFF in other instances.
- MEF: This instruction turns ON at the falling edge of the operation result up to the MEF instruction and turns OFF in other instances.

| Ladder diagram                                                                    | Structured text                        |
|-----------------------------------------------------------------------------------|----------------------------------------|
|  | <pre>ENO:=MEP(EN); ENO:=MEF(EN);</pre> |

## FBD/LD

6

## Processing details

### MEP

- This instruction turns ON (conductive state) at the rising edge (OFF to ON) of the operation result up to this instruction. This instruction turns OFF (non-conductive state) in instances other than the rising edge of the operation result up to this instruction.
- Use of this instruction makes conversion to pulse easier when multiple contacts are connected in series.

### MEF

- This instruction turns ON (conductive state) at the falling edge (ON to OFF) of the operation result up to this instruction. This instruction turns OFF (non-conductive state) in instances other than the falling edge of the operation result up to this instruction.
- Use of this instruction makes conversion to pulse easier when multiple contacts are connected in series.

## Operation error

There is no operation error.

### Point

- If an indexed contact is converted to pulse by the subroutine program and the FOR to NEXT instructions, etc., these instructions may not function properly.
- These instructions operate using the operation result so far. Hence, use them at the same position as the AND instruction. These instructions cannot be used at positions where the LD and OR instructions are programmed.

## 6.3 Output Instructions

### Out (excluding the timer, counter and annunciator)

#### OUT

**FX5S****FX5UJ****FX5U****FX5UC**

This instruction outputs the operation result up to this instruction to the specified device.

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=OUT(EN,d); |
| FBD/LD                                                                            |                 |

When using C, refer to  Page 135 OUT C.

\*3 Only the FX5 intelligent function module can be specified.

\*4 When using LC, refer to  Page 137 OUT LC.

#### Processing details

- This instruction outputs the operation result up to this instruction to the specified device.

| Condition                            | Operation result | Coil/specified bit |
|--------------------------------------|------------------|--------------------|
| When bit device is used              | OFF              | OFF                |
|                                      | ON               | ON                 |
| When bit of word device is specified | OFF              | 0                  |
|                                      | ON               | 1                  |

## Program example

Timing chart

## Operation error

There is no operation error.

# Timer

## OUT T, OUTH T, OUTHS T, OUT ST, OUTH ST, OUTHS ST

FX5S

FX5UJ

FX5U

FX5UC

The timer counts up to the set value when the operation result up to the OUT instruction is ON and the coil of the timer/retentive timer specified by (d) turns ON. When the timer times up, NO contact becomes conductive and NC contact becomes non conductive.

| Ladder diagram                                                                    | Structured text                                                                            |
|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
|  | <pre>ENO:=OUT_T(EN,Coil,Value); ENO:=OUTH(EN,Coil,Value); ENO:=OUTHS(EN,Coil,Value);</pre> |
| FBD/LD                                                                            |                                                                                            |
|  |                                                                                            |
| ("OUT_T", "OUTH", "OUTHS" enters □.)                                              |                                                                                            |

## Setting data

### ■Descriptions, ranges, and data types

| Operand                   | Description         | Range      | Data type                            | Data type (label)   |
|---------------------------|---------------------|------------|--------------------------------------|---------------------|
| (d) <sup>*1</sup>         | Timer Number        | —          | Timer/retentive timer                | ANY <sup>*3</sup>   |
| (Set value) <sup>*2</sup> | Timer set value     | 0 to 32767 | 16-bit unsigned binary <sup>*4</sup> | ANY16 <sup>*4</sup> |
| EN                        | Execution condition | —          | Bit                                  | BOOL                |
| ENO                       | Execution result    | —          | Bit                                  | BOOL                |

\*1 In the case of the ST language and the FBD/LD language, d displays as Coil.

\*2 In the case of the ST language and the FBD/LD language, Set value displays as Value.

\*3 Only timer type/retentive timer type label can be used.

\*4 In the case of the OUT\_T instruction of the ST language and the FBD/LD language, data type is ANY\_INT.  
Digit specified bit type label cannot be used.

### ■Applicable devices

| Operand     | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant        |   |    | Others |
|-------------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|-----------------|---|----|--------|
|             | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H            | E | \$ |        |
| (d)         | —                           | ○ <sup>*1</sup>           | —     | — | —           | —  | —                      | —               | — | —  | —      |
| (Set value) | —                           | ○ <sup>*2</sup>           | ○     | — | —           | —  | —                      | ○ <sup>*3</sup> | — | —  | —      |

\*1 Only T and ST can be used.

\*2 T, ST, and C cannot be used.

\*3 Only decimal constant (K) can be used.

## Processing details

- These instructions count up to the set value when the operation result up to the OUT instruction is ON and the coil of the timer/retentive timer specified by (d) turns ON. When the timer reaches the end of its count (current value  $\geq$  set value), NO contact becomes conductive and NC contact becomes non-conductive.
- Operation is as follows when the operation result up to the OUT instruction changes from ON to OFF.

| Timer type      | Timer coil | Current timer value | Before time-out      |                  | After time-out       |                      |
|-----------------|------------|---------------------|----------------------|------------------|----------------------|----------------------|
|                 |            |                     | NO contact           | NC contact       | NO contact           | NC contact           |
| Timer           | off        | 0                   | Non-Conductive state | Conductive state | Non-Conductive state | Conductive state     |
| Retentive timer | off        | Holds current value | Non-Conductive state | Conductive state | Conductive state     | Non-Conductive state |

- After the timer times up, clear the current value of the retentive timer and turn the contact off by the RST instruction.
- The following processing is executed when the OUT instruction is executed:
  - The coil in the OUT T, OUTH T, OUTHS T, OUT ST, OUTH ST and OUTHS ST instructions turns ON/OFF
  - The contact in the OUT T, OUTH T, OUTHS T, OUT ST, OUTH ST and OUTHS ST instructions turns ON/OFF
  - The current value in the OUT T, OUTH T, OUTHS T, OUT ST, OUTH ST and OUTHS ST instructions changes
- When the OUT T instruction is skipped using the CJ instruction, etc. while the OUT T and OUT ST instructions are ON, these instructions do not update the current value or turn ON/OFF the contacts.
- When the same OUT T and OUT ST instructions are executed in the same scan twice or more, these instructions update the current value for the same number of times of execution.

### Point

Values used for timers can be set in the range 1 to 32767. Actual timer constants are as follows since the OUT, OUTH, and OUTHS instructions operate as 100 ms, 10 ms, and 1 ms timers, respectively.

- OUT instruction: 0.1 to 3276.7 seconds
- OUTH instruction: 0.01 to 327.67 seconds
- OUTHS instruction: 0.001 to 32.767 seconds

For the counting method, refer to the following.

 MELSEC iQ-F FX5 User's Manual (Application)

## Program example

The set value is required after OUT instruction for the coil of a timer or counter.

The set value can be specified directly by a decimal number (K) or indirectly using a data register (D) or file register (R).

- Direct specification

The set value of a timer or counter can be specified directly by a decimal number (K).

- Indirect specification

The set value of a timer or counter can be set by a data register (D) or file register (R). At this time, the current value of the data register (D) or file register (R) is regarded as the set value of the timer or counter.

It is necessary to write the set value to a data register (D) or file register (R) used for the set value by MOV instruction, DSW instruction or indicator before driving the timer or counter.

- Indexing

Devices used in OUT instruction can be indexed with index registers (Z and LZ).

(State relays (S), long counter (LC), and "D□.b" cannot be indexed.)

24 words in total as the number of points of Z and LZ are available for indexing.

When a used device is an input (X) or output (Y), the value of an index register (Z and LZ) is converted into an octal number, and then added.

Example: When the value of Z0 is 20, Y24 turns ON or OFF.

- Bit specification of word devices

A bit in data register (D) can be specified as a device used in OUT instruction.

When specifying a bit in data register, input "." after a data register (D) number, and then input a bit number (0 to F) consecutively.

Only 16-bit data registers are available.

Specify a bit number as "0, 1, 2, ... 9, A, B, ... F" from the least significant bit.

Example: In the example shown on the left, the bit 3 of D0 turns ON or OFF when X0 turns ON or OFF.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                        |
|----------------------------|----------------------------------------------------|
| 3405H                      | A negative value is specified for the timer value. |

# Counter

## OUT C

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction increments the current value of the counter specified by (d) by 1 when the operation result up to OUT instruction changes from OFF to ON, and when the counter reaches the end of its count, NO contact becomes conductive and NC contact becomes non-conductive.

| Ladder diagram                                                                                        | Structured text            |

- \*1 Only C can be used.
- \*2 T, ST, and C cannot be used.
- \*3 Only decimal constant (K) can be used.

## Processing details

- This instruction increments the current value of the counter specified by (d) by 1 when the operation result up to OUT instruction changes from OFF to ON, and when the counter reaches the end of its count (current value  $\geq$  set value), NO contact becomes conductive and NC contact becomes non-conductive.
- The counter does not count while the operation result remains on. (Count input does not need to be converted to pulses.)
- After a count up, the count value and contact status do not change until the RST instruction is executed.
- When the set value is 0, the same processing as for set value 1 is performed.

## Operation error

\*1 T, ST, and C cannot be used.

\*2 Only decimal constant (K) can be used.

## Processing details

- This instruction increments the current value of the long counter specified by (d) by 1 when the operation result up to the OUT instruction changes from OFF to ON, and when the counter reaches the end of its count (current value  $\geq$  set value), NO contact becomes conductive and NC contact becomes non-conductive.
- The counter does not count while the operation result remains on. (Count input does not need to be converted to pulses.)
- After a count up, the count value and contact status do not change until the RST or ZRST instruction is executed.
- When the set value is 0, the same processing as for set value 1 is performed.
- When signed (-2147483648 to + 2147483647) or high speed counter is assigned to the LC, the UDCNTF instruction is used. For the UDCNTF instruction, refer to  Page 774 UDCNTF.

## Operation error

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                      | Range | Data type | Data type (label) |
|---------|----------------------------------|-------|-----------|-------------------|
| (d)     | Annunciator number that turns ON | —     | Bit       | —*1 (ANY_BOOL)    |
| EN      | Execution condition              | —     | Bit       | BOOL              |
| ENO     | Execution result                 | —     | Bit       | BOOL              |

\*1 Regardless of the program language to be used, the data type is specified by a device. Do not specify a label.

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (d)     | ○*1                         | —                         | —     | — | —           | —  | —                      | —        | — | —  | —      |

\*1 Only F can be used.

### Processing details

- This instruction outputs the operation result up to the OUT F instruction to the specified annunciator.
- Operation is as follows when annunciator (F) is turned ON by the OUT F instruction.
  - The annunciator number (F number) that turns ON is stored in special registers (SD64 to SD79).
  - The content of SD63 is incremented by 1.
- When the content of SD63 is 16 (16 annunciators are already on), the annunciator number that turns ON is not stored in SD64 to SD79 even if a new annunciator turns ON.
- Operation is as follows when annunciator (F) is turned OFF by the OUT F instruction:
  - The coil turns OFF, but the contents of SD64 to SD79 do not change.
  - To delete an annunciator that has turned OFF by the OUT F instruction from SD64 to SD79, use the RST F instruction.

|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |             |
| (d)     | ○*1                         | ○*2                       | ○*3   | — | —           | —  | —                      | —        | — | —  | ○           |

- \*1 When using F, refer to  Page 145.
- \*2 T, ST, and C cannot be used.
- \*3 Only the FX5 intelligent function module can be used.

## Processing details

- The status of the specified device changes as follows when the execution command turns ON.

| Device                           | Device status                |
|----------------------------------|------------------------------|
| Bit devices                      | Turns coils and contacts ON. |
| Bit specification of word device | Sets the specified bit to 1. |

- A device that is turned ON is held on even if the execution command turns OFF. Devices that are turned ON by the SET instruction can be turned OFF by the RST instruction.

- When the execution command is OFF, the device status does not change.

## Precautions

When the SET and RST instructions are executed on the same output relay (Y), the result of the instruction nearer the END instruction (end of program) is output.

## Operation error

There is no operation error.

# Resetting devices (excluding annunciator)

## RST

FX5S

FX5UJ

FX5U

FX5UC

The status of the device specified by (d) changes as follows when the RST input turns ON.

- Bit devices: Turns the coils and contacts OFF.
- Timers, counters: Sets the current value to 0, and turns contacts OFF.
- Bit specification of word device: Sets the specified bit to 0.
- Word devices, module access devices, index registers: Sets content to 0.

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=RST(EN,d); |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                                                        | Range | Data type            | Data type (label) |
|---------|----------------------------------------------------------------------------------------------------|-------|----------------------|-------------------|
| (d)     | Bit device number/ bit specification of word device to be reset, or word device number to be reset | —     | Bit/word/double word | ANY_ELEMENTARY*1  |
| EN      | Execution condition                                                                                | —     | Bit                  | BOOL              |
| ENO     | Execution result                                                                                   | —     | Bit                  | BOOL              |

\*1 Digit specified bit type label cannot be used.

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (DY) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |             |
| (d)     | ○*1                         | ○                         | ○*2   | ○ | ○           | ○  | ○                      | —        | — | —  | ○           |

\*1 When using F, refer to  Page 147.  
Digit specified bit device cannot be used.

\*2 Only the FX5 intelligent function module can use digit specification of bit devices.

## Processing details

- The status of the specified device changes as follows when the execution command turns ON.

| Device                                              | Device status                                        |
|-----------------------------------------------------|------------------------------------------------------|
| Bit devices                                         | Turns coils and contacts OFF.                        |
| Timers, counters                                    | Sets the current value to 0, and turns contacts OFF. |
| Bit specification of word device                    | Set the specified bit to 0.                          |
| Word devices, module access device, index registers | Sets content to 0.                                   |

- When the execution command is OFF, the device status does not change.

- Function when a word device is specified by the RST instruction is the same as the following circuit.

## Precautions

When the RST instruction for a timer or counter is executed by a program containing a jump or by a subroutine program or interrupt program, the timer or counter is held in a reset state, and the timer or counter may not work normally.

## Operation error

There is no operation error.

# Setting annunciator

## SET F

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction turns ON the specified annunciator.

| ("RST" enters □.)                                                                 |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                 | Range | Data type | Data type (label) |
|---------|---------------------------------------------|-------|-----------|-------------------|
| (d)     | Annunciator number (F number) that is reset | —     | Bit       | ANY_ELEMENTARY    |
| EN      | Execution condition                         | —     | Bit       | BOOL              |
| ENO     | Execution result                            | —     | Bit       | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (d)     | ○*1                         | —                         | —     | — | —           | —  | —                      | —        | — | —  | —      |

\*1 Only F can be used.

## Processing details

- This instruction turns OFF the annunciator specified by (d) when the execution command turns ON.
- An annunciator number (F number) that turns OFF is deleted from special registers (SD64 to SD79) and the content of SD63 is decremented by 1.
- When the content of SD63 is 16, annunciator numbers are deleted from SD64 to SD79 by the RST instruction. Also, if an annunciator not registered in SD64 to SD79 turns ON, its number is registered. When there are two or more unregistered numbers, this instruction adds the numbers starting from the smallest annunciator number. SD63 is not decremented by 1 when the numbers not registered in SD64 to SD79 are turned OFF.

(1): F90 is reset.

(2): When F number that is not registered in SD79 is stored, this remains as 16. When SD79 is 0, the number is decremented by -1 to become 15.

(3): The F number in SD66 is shifted to this area.

(4): F number of SD67 is stored.

(5): Not registered F number or 0 is stored.

\*1 Only T can be used.

\*2 Only F can be used.

### Processing details

- This instruction sets (d) when the command input remains ON continuously for the evaluation time [(n)×100 ms, (s)] or more. This instruction resets the current value of (s) evaluation timer and does not set (d) when the command time is less than the evaluation time [(n)×100 ms]. Also, this instruction resets the evaluation timer when the command input turns OFF.

- (1): Less than the evaluation time ((n) × less than 100 ms)  
(2): Equivalent to or longer than the evaluation time ((n) × 100 ms or more)

## ■Related devices

| Device | Name                                          | Description                                                        |
|--------|-----------------------------------------------|--------------------------------------------------------------------|
| SM8049 | ON status annunciator smallest number enabled | When SM8049 is turned ON, SM8048 and SD8049 are enabled.           |
| SM8048 | Annunciator operation                         | When one of the F devices is operating, SM8048 turns ON.           |
| SD8049 | ON status annunciator smallest number         | The smallest number of the F devices that are operating is stored. |

## Program example

- Displaying a fault number using an annunciator

When the program for external fault diagnosis shown below is created and the content of SD8049 (smallest state relay number in the ON status) is monitored, the smallest state relay number in the ON status from F90 to F92 is displayed.

If two or more faults are present at the same time, the next smallest fault number is displayed after the fault of the smallest fault number is cleared.

## Operation error

There is no operation error.

# Resetting annunciator (smallest number reset)

## ANR(P)

- FX5S
- FX5UJ
- FX5U
- FX5UC

This instruction resets the lowest number annunciator (F device) in the ON status.

| Ladder diagram                                                                    | Structured text                 |
|-----------------------------------------------------------------------------------|---------------------------------|
|  | ENO:=ANR(EN);<br>ENO:=ANRP(EN); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Processing details

• Annunciator (F device) that is operating (in ON status) is reset when the command input turns ON.  
This instruction resets the annunciator with the smallest number when multiple annunciators are ON. If the command input is turned ON again, this instruction resets the annunciator with the next smallest number among annunciators (F devices) that are operating.

### Related devices

| Device | Name                                          | Description                                                        |
|--------|-----------------------------------------------|--------------------------------------------------------------------|
| SM8049 | On status annunciator smallest number enabled | When SM8049 is turned ON, SM8048 and SD8049 are enabled.           |
| SM8048 | Annunciator operation                         | When one of the F devices is operating, SM8048 turns ON.           |
| SD8049 | On status annunciator smallest number         | The smallest number of the F devices that are operating is stored. |

### Precautions

- When ANR instruction is used, annunciators in the ON status are reset in turn in each operation cycle.
- This is executed for only 1 operation cycle (only once) when the ANRP instruction is used.

### Program example

For a program example, refer to  Page 149 Setting annunciator (with check time).

### Operation error

There is no error.

# Rising edge output

## PLS

FX5S    FX5UJ    FX5U    FX5UC

This instruction turns ON the device specified by (d) for one scan when the PLS command turns from OFF to ON, and turns OFF in other cases.

**Ladder diagram**

**Structured text**  
ENO:=PLS(EN,d);

**FBD/LD**

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                     | Range | Data type | Data type (label) |
|---------|---------------------------------|-------|-----------|-------------------|
| (d)     | Device to be converted to pulse | —     | Bit       | ANY_BOOL          |
| EN      | Execution condition             | —     | Bit       | BOOL              |
| ENO     | Execution result                | —     | Bit       | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (DY) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |             |
| (d)     | ○                           | ○*1                       | ○*2   | — | —           | —  | —                      | —        | — | —  | ○           |

\*1 T, ST, and C cannot be used.  
\*2 Only the FX5 intelligent function module can be used.

## Processing details

- This instruction turns ON the specified device for one scan when the PLS command turns from OFF to ON, and turns OFF in other cases. When there is one PLS instruction programmed for the device specified by (d) during a scan, the specified device turns ON for one scan.

Sc: 1 scan

- If the RUN/STOP/RESET switch is changed from RUN to STOP after execution of the PLS instruction, the PLS instruction will not be executed even if the switch is set to RUN again.

(1) 1 scan of PLS M0

(2) CPU module operation stop time

(3) Set the RUN/STOP/RESET switch on the CPU module to RUN→STOP.

(4) Set the RUN/STOP/RESET switch on the CPU module to STOP→RUN.

## Precautions

- When write during RUN is completed for a circuit including a rising edge instruction (LDP/ANDP/ORP instruction), the instruction is not executed regardless of the ON/OFF status of the target device of the rising edge instruction. Also, in the case of a rising edge instruction (PLS instruction), the instruction is not executed regardless of the ON/OFF status of the device that is set as the operation condition. The instruction is executed when the target device and the device in the operation conditions is set from OFF to ON again.
- Note that the device specified by (d) sometimes turns ON for one scan or more when the PLS instruction is made to jump by the CJ instruction or the executed subroutine program was not called by the CALL(P) instruction.

## Program example

Timing chart

In the figure above, M0 is ON during only one operation cycle when X0 changes from OFF to ON.

## Operation error

There is no operation error.

# Falling edge output

## PLF

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction turns ON the device specified by (d) for one scan when the PLF command turns from ON to OFF, and turns OFF in other cases.

**Structured text**  
ENO:=PLF(EN,d);

**FBD/LD**

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                     | Range | Data type | Data type (label) |
|---------|---------------------------------|-------|-----------|-------------------|
| (d)     | Device to be converted to pulse | —     | Bit       | ANY_BOOL          |
| EN      | Execution condition             | —     | Bit       | BOOL              |
| ENO     | Execution result                | —     | Bit       | BOOL              |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (DY) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|-------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |             |
| (d)     | ○                           | ○*1                       | ○*2   | — | —           | —  | —                      | —        | — | —  | ○           |

\*1 T, ST, and C cannot be used.  
\*2 Only the FX5 intelligent function module can be used.

### Processing details

- This instruction turns ON the specified device for one scan when the PLF command turns OFF from ON, and turns OFF in other cases. When there is one PLF instruction programmed for the device specified by (d) during a scan, the specified device turns ON for one scan.

Sc: 1 scan

- If the RUN/STOP/RESET switch is changed from RUN to STOP after execution of the PLF instruction, the PLF instruction will not be executed even if the switch is set to RUN again.

## Precautions

- When write during RUN is completed for a circuit including a falling edge instruction (LDF/ANDF/ORF instruction), the instruction is not executed regardless of the ON/OFF status of the target device of the falling edge instruction. Also, in the case of a falling edge instruction (PLF instruction), the instruction is not executed regardless of the ON/OFF status of the device that is set as the operation condition. The instruction is executed when the target device and the device in the operation conditions is set from ON to OFF again.
- Note that the device specified by (d) sometimes turns ON for one scan or more when the PLF instruction is made to jump by the CJ instruction or the executed subroutine program was not called by the CALL(P) instruction.

## Operation error

There is no operation error.

# Inverting the bit device output

## FF

FX5S

FX5UJ

FX5U

FX5UC

This instruction reverses the output status of the device specified by (d) when the execution command changes from OFF to ON.

\*1 T, ST, and C cannot be used.

\*2 Only the FX5 intelligent function module can be used.

## Processing details

### ■Alternating output (1-step)

The bit device specified by (d) is reversed ON ↔ OFF each time the command input changes from OFF to ON.

### ■Division output (according to alternating output (2-step))

The ALTP instruction can be used in multiple combinations to perform division output.

(1): Specify the same device

## Precautions

When the CPU module is programmed with the ALT instruction, reversal operation is performed at every operation cycle. To perform reversal operation by command ON/OFF, either use the ALTP instruction (pulse execution type) or set a command contact as LDP etc. (pulse execution type).

## Operation error

There is no operation error.

# 6.4 Shift Instructions

## Shifting bit devices

### SFT(P)

- FX5S
- FX5UJ
- FX5U
- FX5UC

- In case of bit device:  
These instructions shift the ON/OFF status of the device before the device specified by (d) to the device specified by (d).
- When bit of word device is specified:  
These instructions shift the 1/0 status of the bit before the bit specified by (d) to the bit specified by (d).

| Ladder diagram                                                                    | Structured text                     |

## Processing details

### ■In case of bit device

- This instruction shifts the ON/OFF status of the device before the device specified by (d) to the device specified by (d). The device before the device specified by (d) turns OFF.

#### Ex.

When M11 is specified by the SFTP instruction and the SFTP instruction is executed, the ON/OFF status of M10 is shifted to M11 and M10 is turned OFF.

- Turn ON the first device to be shifted by the SET instruction.
- When the SFT(P) instruction is used consecutively, create the program to start from the device with the largest number.

### ■When bit of word device is specified:

- This instruction shifts the 1/0 status of the bit before the bit specified by (d) to the bit specified by (d). The bit before the bit specified by (d) becomes 0.

#### Ex.

When D0.5 (bit 5 (b5) of D0) is specified by the SFT(P) instruction and the SFT(P) instruction is executed, the 1/0 status of b4 of the D0 is shifted to b5 and b4 is set to 0.

## Processing details

- This instruction shifts the 16-bit data in the device specified by (d) to the right by (n) bit(s) from the most significant bit. The (n) bit(s) from the most significant bit is/are filled with 0(s).

When (n)=6

- When (d) is a bit device, bits are shifted to the right within the device range specified by digit specification.

When (n)=4

- Specify any value between 0 and 15 for (n). If a value 16 or larger is specified for (n), bits are shifted to the right by the remainder value of  $(n) \div 16$ . For example, when (n) is 18, data is shifted by 2 bits to the right because 18 divided by 16 equals 1 with a remainder of 2.

## ■Related devices

| Device | Name  | Description                                              |
|--------|-------|----------------------------------------------------------|
| SM700  | Carry | ON/OFF according to the status (1/0) of the (n-1)th bit. |
| SM8022 |       |                                                          |

## Program example

In the program example shown below, the contents of Y10 to Y23 are shifted rightward by the number of bits specified by D0 when X20 turns ON.

## Operation error

There is no operation error.

## Processing details

- These instructions shift the 16-bit data in the device specified by (d) to the left by (n) bit(s) from the least significant bit. (n) bits from the least significant bit are filled with "0".

When (n)=8

- When (d) is a bit device, bit(s) are shifted to the left within the device range specified by digit specification.

When (n)=3

- Specify any value between 0 and 15 for (n). If a value 16 or larger is specified for (n), bit(s) are shifted to the left by the remainder value of  $(n) \div 16$ . For example, when (n) is 18, data is shifted by 2 bits to the left because 18 divided by 16 equals 1 with a remainder of 2.

\*1 T, ST, and C cannot be used.

\*2 Only 0 or 1 can be used.

## Processing details

- These instructions shift (n1) bits of data to the right by (n2) bit(s) from the device specified by (d). After the shift, (n2) points from (s) are set into (n2) points from (d)+(n1-n2).
- When K0 is specified for (s), set 0s for (n2) points of bits from (d)+(n1-n2) after the shift.
- When K1 is specified for (s), set 1s for (n2) points of bits from (d)+(n1-n2) after the shift.

(1): When (s)=K0, it is 0.

## Operation error

## Processing details

- This instruction shifts (n1) words of data to the right by (n2) word(s) from the device specified by (d). After the shift, (n2) points from (s) are set into (n2) points from (d)+(n1-n2).
- This instruction sets the specified value for (n2) points of devices from (d) + (n1-n2) after the shift when K is specified for (s).

- When the value specified for (n1) or (n2) is 0, the processing is not performed.

## Program example

- Shifting devices with digit specification

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

These instructions create program with efficient ladder switching by opening/closing common buses in ladders.

Ladder using master control is illustrated below.

(Left: Display on the engineering tool, Right: Actual operation)

(1) Executed only when X0 is on

### ■MC

- When the execution command of the MC instruction turns ON at the start of master control, the operation result between the MC and MCR instructions is as per the instructions (according to ladder). When the execution command of MC instruction turns OFF, the operation result between the MC and MCR instructions becomes as follows.

| Device                                                                                                                         | Device status                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Timer                                                                                                                          | The count value becomes 0, and both coils and contacts turn OFF.                       |
| Counters, retentive timers                                                                                                     | Coils turn OFF but the current status of both count values and contacts is maintained. |
| Devices in OUT instruction                                                                                                     | Forcibly turned OFF.                                                                   |
| Devices in SET and RST instructions<br>Devices in SFT(P) instruction<br>Devices in basic instructions and applied instructions | Current status is maintained.                                                          |

### Point

When an instruction (e.g. FOR to NEXT instructions etc.) not requiring NO contact instruction is programmed in a ladder using master control, the CPU module executes that instruction regardless of the execution command of this instruction.

- With this instruction, the same nesting (N) number can be used as many times as necessary by changing the device specified by (d).
- When this instruction is ON, the coil of the device specified by (d) turns ON. Also, the coil becomes a double coil when the same device is used by the OUT instruction, for example. So, do not use the device specified by (d) in other instructions.

### ■MCR

- This instruction indicates the end of the master control range by the master control release instruction.
- Do not prefix this instruction with NO contact instruction.
- Use these (MC and MCR) instructions with same nesting (N) number as a pair. Note, however, that when this instruction is nested at a single location, all master controls can be ended by just one (N) number, the smallest number. (Refer to Caution.)

Master control instructions can be used in a nested fashion. Each master control section is distinguished by nesting (N). Nesting is available within the range N0 to N14.

A nested structure allows you to create a ladder for successively restricting program execution conditions.

A nested structure ladder is illustrated as follows:

(Left: Display on the engineering tool, Right: Actual operation)

- (1) Executed when A is ON
- (2) Executed when A and B are ON
- (3) Executed when A, B, and C are ON
- (4) Regardless of A, B, and C

## Precautions

- If an instruction (e.g. LD, LDI) to be connected to the bus is not programmed following the MC instruction, a program structure error (error code: 33E0) occurs.
- These instructions cannot be used in FOR to NEXT, STL to RETSTL, P to RET (SRET), and I to IRET. Also, do not block by I, IRET, FEND, END, RET (SRET), RETSTL, etc. Addition by write during RUN mode results in an error.
- Nesting up to 15 levels (N0 to N14) is possible. When nesting instructions, the MC instruction is used starting from the smallest (N) number and the MCR instruction is started starting from the biggest number. Programming in reverse order does not produce a nested structure and hence the CPU module cannot execute operations properly.
- When the MCR instruction is nested at a single location, all master controls can be ended by just one nesting (N) number, the smallest number.

## Operation error

There is no operation error.

# 6.6 Termination Instructions

## Ending the main routine program

### FEND

FX5S    FX5UJ    FX5U    FX5UC

This instruction is used to branch operation of the sequence program by the CJ instruction or to divide the main routine program into a subroutine program or an interrupt program.

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | Not supported.  |
| FBD/LD                                                                            | Not supported.  |

### Processing details

- This instruction branches operation of the sequence program by the CJ instruction or dividing the main routine program into subroutine programs and interrupt programs.
- When this instruction is executed, program execution returns to the program at step 0 after output processing, input processing and refreshing of the watchdog timer.
- The sequence program from this instruction onwards can also be displayed as ladder by the engineering tool.

(Left: When the CJ instruction is used, Right: When there are subroutine programs and interrupt programs)

- A: Main routine program  
B: Subroutine program  
C: Interrupt Program  
(1): Operation when the CJ instruction is not executed  
(2): Jump by the CJ instruction  
(3): Operation when the CJ instruction has been executed

## Program example

- Example in which outputs in the subroutine are latched

In the following program example, the counter C0 is provided to count X1. When X0 is input, the subroutine P0 is executed only in one scan, and then the counter is reset and Y7 is output.

### Timing chart

- Example for resetting outputs in the subroutine

Timing chart

## Operation error

| Error code (SD0/SD8067) | Description                                                                                            |
|-------------------------|--------------------------------------------------------------------------------------------------------|

| FBD/LD                                                                            |                 |
| Not supported.                                                                    |                 |

### Processing details

- This instruction indicates the end of all programs including the main routine program, subroutine program, and interrupt program. When this instruction is executed, the CPU module ends execution of the currently executing program.

(1): Sequence program

- The first time the RUN is started, execution begins from this instruction.
- This instruction cannot be programmed midway during the main sequence program. When this processing is required midway during the program, use the FEND instruction.
- When programming is performed using the engineering tool in ladder edit mode, the END instruction is automatically input and cannot be edited.
- The following illustrates how the END and FEND instructions are used properly when a program contains a main routine program, subroutine program, and interrupt program.

- A: Main routine program  
B: Subroutine program  
C: Interrupt Program  
D: Main sequence program area  
(1): FEND instruction is required.  
(2): END instruction is required.

The END instruction executed while a program is divided into multiple program blocks indicates the end of a program block.

The END instruction executed for END processing is executed at the end of the last executed program registered in the program settings.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------|
| 3340H                      | The END instruction is executed before the NEXT instruction after the FOR instruction is executed.    |
| 3381H                      | The END instruction is executed before the RET instruction after the CALL(P) instruction is executed. |
| 33E3H                      | The END instruction is programmed between FOR-NEXT.                                                   |
| 33E4H                      | The END instruction is programmed between MC-MCR.                                                     |
| 33E5H                      | The END instruction is programmed between STL-RETSTL.                                                 |
| 33E7H                      | The END instruction is programmed between I-IRET.                                                     |

# 6.7 Stop Instruction

## Stopping the sequence program

### STOP

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction resets outputs (Y) and stops operation of the CPU module when the execution command turns ON. (This operation is the same as setting the switch to STOP.)

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=STOP(EN);  |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Processing details

- This instruction resets outputs (Y) and stops operation of the CPU module when the execution command turns ON. (This operation is the same as setting the switch to STOP.)
- To restart operation of the CPU module after this instruction is executed, return the switch from RUN→STOP and set it to RUN again.

### Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 3340H                      | The STOP instruction is executed before the NEXT instruction is executed after the FOR instruction is executed.                |
| 3381H                      | The STOP instruction is executed before the RET instruction is executed after the CALL(P) or XCALL(P) instruction is executed. |
| 3582H                      | The STOP instruction is executed before the IRET instruction is executed in the interruption program.                          |

# 7 BASIC INSTRUCTIONS

## 7.1 Comparison Operation Instructions

### Comparing 16-bit binary data

LD□(\_U), AND□(\_U), OR□(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions perform a comparison operation between the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2). (Devices are used as NO contacts.)

| Ladder diagram                                                 | Structured text <sup>*1</sup>                                               |
|----------------------------------------------------------------|-----------------------------------------------------------------------------|
|                                                                | ENO:=LD_□(EN,s1,s2);<br>ENO:=AND_□(EN,s1,s2);<br>ENO:=OR_□(EN,s1,s2);       |
|                                                                | ENO:=LD_□_U(EN,s1,s2);<br>ENO:=AND_□_U(EN,s1,s2);<br>ENO:=OR_□_U(EN,s1,s2); |
|                                                                | ("EQ", "NE", "GT", "LE", "LT", "GE" enters □.) <sup>*2</sup>                |
| ("=_U", ">(_U)", ">(_U)", "<=_U)", "<(_U)", ">=_U)" enters □.) |                                                                             |

#### FBD/LD

("\_EQ(\_U)", "\_NE(\_U)", "\_GT(\_U)", "\_LE(\_U)", "\_LT(\_U)", "\_GE(\_U)" enters □.)<sup>\*2</sup>

<sup>\*1</sup> Supported by engineering tool version "1.035M" and later.

<sup>\*2</sup> EQ is =, NE is <>, GT is >, LE is <=, LT is <, and GE is >=.

#### Setting data

#### ■ Descriptions, ranges, and data types

| Operand | Description          | Range            | Data type              | Data type (label) |
|---------|----------------------|------------------|------------------------|-------------------|
| (s1)    | LD□, AND□, OR□       | -32768 to +32767 | 16-bit signed binary   | ANY16_S           |
|         | LD□_U, AND□_U, OR□_U | 0 to 65535       | 16-bit unsigned binary | ANY16_U           |
| (s2)    | LD□, AND□, OR□       | -32768 to +32767 | 16-bit signed binary   | ANY16_S           |
|         | LD□_U, AND□_U, OR□_U | 0 to 65535       | 16-bit unsigned binary | ANY16_U           |
| EN      | Execution condition  | —                | Bit                    | BOOL              |
| ENO     | Execution result     | —                | Bit                    | BOOL              |

## ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s1)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions perform a comparison operation between the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2). (Devices are used as NO contacts.)
- The following table lists the comparison operation results of each instruction.

| Instruction symbol | Condition | Result               |
|--------------------|-----------|----------------------|
| =(_U)              | (s1)=(s2) | Conductive state     |
| <>(_U)             | (s1)≠(s2) |                      |
| >(_U)              | (s1)>(s2) |                      |
| <=(_U)             | (s1)≤(s2) |                      |
| <(_U)              | (s1)<(s2) |                      |
| >=(_U)             | (s1)≥(s2) |                      |
| =(_U)              | (s1)≠(s2) | Non-conductive state |
| <>(_U)             | (s1)=(s2) |                      |
| >(_U)              | (s1)≤(s2) |                      |
| <=(_U)             | (s1)>(s2) |                      |
| <(_U)              | (s1)≥(s2) |                      |
| >=(_U)             | (s1)<(s2) |                      |

## Precautions

- When the most significant bit is "1" in the data stored in (s1) or (s2), it is regarded as a negative binary value for comparison. (Excluding unsigned operation)

## Program example

### • LD□(\_U)

### • AND□(\_U)

### • OR□(\_U)

## Operation error

There is no operation error.

# Comparing 32-bit binary data

7

## Precautions

- When the most significant bit is "1" in the data stored in (s1) or (s2), it is regarded as a negative binary value for comparison. (Excluding unsigned operation)
- For comparison of 32-bit counter (LC), specify an instruction (LDD=, etc.) that handles 32-bit data. If an instruction (LD=, etc.) that handles 16-bit data is specified, a program error or operation error occurs. (Same applies for index device (LZ) as well.)

## Program example

For a program example, refer to  Page 189 Comparing 16-bit binary data.

## Operation error

There is no operation error.

# Comparison output 16-bit binary data

## CMP(P)(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions perform a comparison operation between the 16-bit binary data in the devices specified by (s1) and (s2).

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions perform a comparison operation between the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2) and according to the result (small, equal, large), (d), (d) + 1, or (d) + 2 is turned ON.
- (s1) and (s2) are handled as binary values within the range of above data setting.
- Large and small comparison is executed algebraically.
  - With sign...-10 (FFF6H) < 2 (0002H)
  - Without sign...32767 (7FFFH) < 65280 (FF00H)

(1): Even if the command input turns OFF and the CMP instruction is not executed, (d) to (d)+2 latches the status just before the command input turns from ON to OFF.

## Precautions

Three devices are occupied from the device specified in (d). Make sure that these devices are not used in other controls.

## Program example

- When comparing the current value of a counter

If it is necessary to clear the comparison result when the instruction is not executed, add the following contents under the above program.

## Operation error

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions perform a comparison operation on the 32-bit binary data in the device specified by (s1) and the 32-bit binary data in the device specified by (s2) with the 32-bit binary data in the device specified by comparison source (s3), and according to the comparison result (below, within zone, above), (d), (d) + 1, or (d) + 2 is turned ON. (s1), (s2), and (s3) are handled as binary values within the range of above data setting.
- Large and small comparison is executed algebraically.
  - With sign...-125400 (FFFE1628H) < 22466 (000057C2H) < 1015444 (000F7E94H)
  - Without sign...0 (00000000H) < 2147483647 (7FFFFFFFH) < 4026531840 (F0000000H)

(1): Even if the command input turns OFF and the DZCP instruction is not executed, (d) to (d)+2 latches the status just before the command input turns from ON to OFF.

## Precautions

- Set (s1) to a value less than (s2).
- Three devices are occupied from the device specified in (d). Make sure that these devices are not used in other controls.

## Operation error

<sup>\*1</sup> T, ST, and C cannot be used.

## Processing details

- These instructions perform a comparison operation between (n) point(s) of 16-bit binary data in the device starting from the one specified by (s1) and (n) point(s) of 16-bit binary data in the device starting from the one specified by (s2), and store the comparison result in (n) point(s) of data starting from the device specified by (d).
- The relevant devices of (n) point(s) of data starting from the device specified by (d) are turned ON when the comparison conditions are met and turned OFF when the comparison conditions are not met.

- Comparison operation is performed in units of 16 bits.
- A constant can be directly specified in (s1).

- The following table lists the comparison operation results of each instruction.

| Instruction symbol | Condition | Result |
|--------------------|-----------|--------|
| BKCMPE=(P)_U       | (s1)=(s2) | On(1)  |
| BKCMPE<>(P)_U      | (s1)≠(s2) |        |
| BKCMPE>(P)_U       | (s1)>(s2) |        |
| BKCMPE<=(P)_U      | (s1)≤(s2) |        |
| BKCMPE<(P)_U       | (s1)<(s2) |        |
| BKCMPE>=(P)_U      | (s1)≥(s2) |        |
| BKCMPE=(P)_U       | (s1)≠(s2) | Off(0) |
| BKCMPE<>(P)_U      | (s1)=(s2) |        |
| BKCMPE>(P)_U       | (s1)≤(s2) |        |
| BKCMPE<(P)_U       | (s1)>(s2) |        |
| BKCMPE>=(P)_U      | (s1)≥(s2) |        |
| BKCMPE<=(P)_U      | (s1)<(s2) |        |

- When the comparison operation result is all ON (1) in all (n) point(s) starting from (d), SM704 and SM8090 (block comparison signal) turns ON.

## Program example

- In the program shown below, four 16-bit binary data starting from D100 are compared with four 16-bit binary data starting from D200 by BKCMP= instruction when X20 is set to ON, and the comparison result is stored in four points starting from M10. When the comparison result is "ON (1)" in all of the four points starting from M10, SM8090 turns ON and Y0 is set to ON.

(When all of M10 to M13 are ON, Y0 is set to ON.)

- In the program shown below, the constant K1000 is compared with four data starting from D10 when X10 is set to ON, and the comparison result is stored in b4 to b7 of D0.

## Operation error

| (d)     | ○                           | ○ <sup>*1</sup>           | —     | — | —           | —  | —                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions perform a comparison operation between (n) point(s) of 32-bit binary data starting from the device specified by (s1) and (n) point(s) of 32-bit binary data starting from the device specified by (s2), and store the comparison result in (n) point(s) of data starting from the device specified by (d).
- The relevant devices of (n) point(s) of data starting from the device specified by (d) are turned ON when the comparison conditions are met and turned OFF when the comparison conditions are not met.

- Comparison operation is performed in units of 32 bits.
- A constant can be directly specified in (s1).

- (d) is specified outside the device range of (n) point(s) of data starting from the one specified by (s1) and outside the device range of (n) point(s) of data starting from the one specified by (s2).
- The following table lists the comparison operation results of each instruction.

| Instruction symbol | Condition | Result |
|--------------------|-----------|--------|
| DBKCMP=(P)_U       | (s1)=(s2) | On(1)  |
| DBKCMP<>(P)_U      | (s1)≠(s2) |        |
| DBKCMP>(P)_U       | (s1)>(s2) |        |
| DBKCMP<=(P)_U      | (s1)≤(s2) |        |
| DBKCMP<(P)_U       | (s1)<(s2) |        |
| DBKCMP>=(P)_U      | (s1)≥(s2) |        |
| DBKCMP=(P)_U       | (s1)≠(s2) | Off(0) |
| DBKCMP<>(P)_U      | (s1)=(s2) |        |
| DBKCMP>(P)_U       | (s1)≤(s2) |        |
| DBKCMP<=(P)_U      | (s1)>(s2) |        |
| DBKCMP<(P)_U       | (s1)≥(s2) |        |
| DBKCMP>=(P)_U      | (s1)<(s2) |        |

- When the comparison operation result is all ON (1) in all (n) point(s) starting from (d), SM704 and SM8090 (block comparison signal) turns ON.

## Precautions

If a 32-bit counter (high-speed counter included) is used, make sure to compare using the 32-bit operation (DBKCMP=, DBKCMP>, DBKCMP<, etc.).

## Operation error

### Point

When bit is specified for word device, devices other than the bit-specified word devices where operation result is stored will not change.

## 7.2 Arithmetic Operation Instructions

### Adding 16-bit binary data

+(P)(\_U) instruction and ADD(P)(\_U) instruction can be used for addition of 16-bit binary data.

#### +(P)(\_U) [using two operands]

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

These instructions add the 16-bit binary data in the device specified by (d) and the 16-bit binary data in the device specified by (s), and store the result in the device specified by (d).

#### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description | Range            | Data type              | Data type (label) |
|---------|-------------|------------------|------------------------|-------------------|
| (s)     | +(P)        | -32768 to +32767 | 16-bit signed binary   | ANY16_S           |
|         | +(P)_U      | 0 to 65535       | 16-bit unsigned binary | ANY16_U           |
| (d)     | +(P)        | -32768 to +32767 | 16-bit signed binary   | ANY16_S           |
|         | +(P)_U      | 0 to 65535       | 16-bit unsigned binary | ANY16_U           |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions add the 16-bit binary data in the device specified by (s) to the 16-bit binary data in the device specified by (d), and store the addition result in the device specified by (d).

- When underflow or overflow occurs in the operation result, the following processing is executed. In this case, the carry flag (SM700, SM8022) does not turn ON.

In case of +(P)

In case of +(P)\_U)

## Operation error

There is no operation error.

## + (P) (\_U) [using three operands]

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

These instructions add the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2), and store the result in the device specified by (d).

| Ladder diagram | Structured text                                   |                                                       |

| ENO     | Execution result    | —                | Bit                    | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s1)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions add the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2), and store the addition result in the device specified by (d).

## Relationship between the flag operation and the sign (positive or negative) of a numeric value

| Device        | Name   | Description                                                                                                     |
|---------------|--------|-----------------------------------------------------------------------------------------------------------------|
| SM700, SM8022 | Carry  | When the operation result exceeds the upper limit of the data setting range, the carry flag is turned ON.       |
| SM8020        | Zero   | When the operation result is 0, the zero flag is turned ON.                                                     |
| SM8021        | Borrow | When the operation result is less than the lower limit of the data setting range, the borrow flag is turned ON. |

### Precautions

#### When specifying the same device in the source and destination

The same device number can be specified for both the source and the destination. In this case, note that the addition result changes in every operation cycle if a continuous operation type ADD instruction is used.

#### Difference between ADD(P) instruction, +(P) instruction, and INC(P) instruction in a program for adding "+1"

When ADD(P) instruction is used to add 1 to the contents of D0 every time X1 turns from OFF to ON, ADD(P) instruction is similar to +(P) instruction and INC(P) instruction described later except for the contents shown in the table below

|                              | ADD(P) instruction                      | +(P) instruction, INC(P) instruction |

| (s2)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions subtract the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2), and store the subtraction result in the device specified by (d).

## Relationship between the flag operation and the sign (positive or negative) of a numeric value

| Device        | Name   | Description                                                                                                     |
|---------------|--------|-----------------------------------------------------------------------------------------------------------------|
| SM700, SM8022 | Carry  | When the operation result exceeds the upper limit of the data setting range, the carry flag is turned ON.       |
| SM8020        | Zero   | When the operation result is 0, the zero flag is turned ON.                                                     |
| SM8021        | Borrow | When the operation result is less than the lower limit of the data setting range, the borrow flag is turned ON. |

### Precautions

#### When specifying the same device in the source and destination

The same device number can be specified for both the source and the destination. In this case, note that the subtraction result changes in every operation cycle if a continuous operation type SUB instruction is used.

#### Difference between SUB(P) instruction, -(P) instruction, and DEC(P) instruction in a program for subtracting "-1"

When SUB(P) instruction is used to subtract 1 from the contents of D0 every time X1 turns from OFF to ON, SUB(P) instruction is similar to -(P) instruction and DEC(P) instruction described later except for the contents shown in the table below

|                              | SUB(P) instruction                      | -(P) instruction, DEC(P) instruction |
|------------------------------|-----------------------------------------|--------------------------------------|
| Flag (zero, borrow or carry) | Operates                                | Does not operate                     |
| Operation result             | (s)-1=(d)<br>-32768 → 0 → -1 → -2 → ... | -32768 → +32767 → +32766 → ...       |

### Program example

### Processing details

- These instructions add the 32-bit binary data in the device specified by (s1) and the 32-bit binary data in the device specified by (s2), and store the addition result in the device specified by (d).

## Relationship between the flag operation and the sign (positive or negative) of a numeric value

| Device        | Name   | Description                                                                                                     |
|---------------|--------|-----------------------------------------------------------------------------------------------------------------|
| SM700, SM8022 | Carry  | When the operation result exceeds the upper limit of the data setting range, the carry flag is turned ON.       |
| SM8020        | Zero   | When the operation result is 0, the zero flag is turned ON.                                                     |
| SM8021        | Borrow | When the operation result is less than the lower limit of the data setting range, the borrow flag is turned ON. |

## Precautions

### When DADD instruction is used

When specifying word devices, a device for the lower-order 16-bits is specified first, and then a word device with the next device number is set for the higher-order 16 bits. To prevent number overlap, it is recommended to always specify an even number.

### When specifying the same device in the source and destination

The same device number can be specified for both the source and the destination. In this case, note that the addition result changes in every operation cycle if a continuous operation type ADD instruction is used.

### Difference between DADD(P) instruction, D+(P) instruction, and DINC(P) instruction in a program for adding "+1"

When DADD(P) instruction is used to add 1 to the contents of D0 every time X1 turns from OFF to ON, DADD(P) instruction is similar to D+(P) instruction and DINC(P) instruction described later except for the contents shown in the table below.

|                              | DADD(P) instruction                                                                        | D+(P) instruction, DINC(P) instruction                                          |
|------------------------------|--------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Flag (zero, borrow or carry) | Operates                                                                                   | Does not operate                                                                |
| Operation result             | $(s)+1=(d)$<br>$+2147483647 \rightarrow 0 \rightarrow +1 \rightarrow +2 \rightarrow \dots$ | $+2147483647 \rightarrow -2147483648 \rightarrow -2147483647 \rightarrow \dots$ |

## Operation error

There is no operation error.

# Subtracting 32-bit binary data

D-(P)(\_U) instruction and DSUB(P)(\_U) instruction can be used for subtraction of 32-bit binary data.

## D-(P)(\_U) [using two operands]

FX5S

FX5UJ

FX5U

FX5UC

These instructions subtract the 16-bit binary data in the device specified by (d) and the 16-bit binary data in the device specified by (s), and store the result in the device specified by (d).

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description         | Range                      | Data type              | Data type (label) |
|---------|---------------------|----------------------------|------------------------|-------------------|
| (s1)    | DSUB(P)             | -2147483648 to +2147483647 | 32-bit signed binary   | ANY32_S           |
|         | DSUB(P)_U           | 0 to 4294967295            | 32-bit unsigned binary | ANY32_U           |
| (s2)    | DSUB(P)             | -2147483648 to +2147483647 | 32-bit signed binary   | ANY32_S           |
|         | DSUB(P)_U           | 0 to 4294967295            | 32-bit unsigned binary | ANY32_U           |
| (d)     | DSUB(P)             | —                          | 32-bit signed binary   | ANY32_S           |
|         | DSUB(P)_U           | —                          | 32-bit unsigned binary | ANY32_U           |
| EN      | Execution condition | —                          | Bit                    | BOOL              |
| ENO     | Execution result    | —                          | Bit                    | BOOL              |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s1)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions subtract the 32-bit binary data in the device specified by (s1) and the 32-bit binary data in the device specified by (s2), and store the subtraction result in the device specified by (d).

## ■Relationship between the flag operation and the sign (positive or negative) of a numeric value

| Device        | Name   | Description                                                                                                     |
|---------------|--------|-----------------------------------------------------------------------------------------------------------------|
| SM700, SM8022 | Carry  | When the operation result exceeds the upper limit of the data setting range, the carry flag is turned ON.       |
| SM8020        | Zero   | When the operation result is 0, the zero flag is turned ON.                                                     |
| SM8021        | Borrow | When the operation result is less than the lower limit of the data setting range, the borrow flag is turned ON. |

### Precautions

#### ■When the DSUB instruction is used

When specifying word devices, a device is specified for the lower-order 16-bits first, and then a word device with the next device number is set for the higher-order 16 bits. To prevent number overlap, it is recommended to always specify an even number.

#### ■When specifying the same device in the source and destination

The same device number can be specified for both the source and the destination. In this case, note that the subtraction result changes in every operation cycle if a continuous operation type SUB instruction is used.

#### ■Difference between DSUB(P) instruction, D-(P) instruction, and DDEC(P) instruction in a program for subtracting "-1"

When DSUB(P) instruction is used to subtract 1 from the contents of D0 every time X1 turns from OFF to ON, SUB(P) instruction is similar to D-(P) instruction and DDEC(P) instruction described later except for the contents shown in the table below:

|                              | DSUB(P) instruction                          | D-(P) instruction, DDEC(P) instruction        |
|------------------------------|----------------------------------------------|-----------------------------------------------|
| Flag (zero, borrow or carry) | Operates                                     | Does not operate                              |
| Operation result             | (s)-1=(d)<br>-2147483648 → 0 → -1 → -2 → ... | -2147483648 → +2147483647 → +2147483646 → ... |

### Operation error

There is no operation error.

# Multiplying 16-bit binary data

\*(P)(\_U) instruction and MUL(P)(\_U) instruction can be used for multiplication of 16-bit binary data.

## \*(P)(\_U)

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

These instructions multiply the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the result in the device specified by (d).

| Ladder diagram                                                                    | Structured text <sup>*1</sup>                       |                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------|---------------------------------------------------------|

|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s1)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions multiply the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the multiplication result in the device specified by (d).

- When (d) is a bit device, lower-order bit is specified first.

**Ex.**

Multiplication result when (d) is a bit device

- K1 ... Lower 4 bits (b0 to b3)
- K4 ... Lower 16 bits (b0 to b15)
- K8 ... Lower 32 bits (b0 to b31)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| 2820H                      | The device range specified by (d) exceeds the corresponding device range. |

## MUL(P)(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions multiply the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the result in the device specified by (d).

| Ladder diagram                                                                    | Structured text*1      |                                                     |
|-----------------------------------------------------------------------------------|------------------------|-----------------------------------------------------|
|  | ENO:=MULP(EN,s1,s2,d); | ENO:=MUL_U(EN,s1,s2,d);<br>ENO:=MULP_U(EN,s1,s2,d); |

### FBD/LD\*1

("MULP", "MUL\_U", "MULP\_U" enters □.)

\*1 The MUL instruction is not supported by the ST language and the FBD/LD language. Use MUL of the standard function.

Page 1304 MUL(\_E)

## Setting data

## Processing details

- These instructions multiply the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the multiplication result in the device specified by (d).

- Nibble can be specified ranging from K1 to K8 for (d).

Ex.

For example, when K2 is specified, only the lower-order 8 bits can be obtained out of the product (32 bits).

- (1): Not output  
(2): K2Y0 operation result is output.

■Related flag

| Device | Name | Description                                                 |
|--------|------|-------------------------------------------------------------|
| SM8304 | Zero | When the operation result is 0, the zero flag is turned ON. |

Program example

Operation error

| Error code<br>(SD0/SD8067) | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| 2820H                      | The device range specified by (d) exceeds the corresponding device range. |

# Dividing 16-bit binary data

/P)(\_U) instruction and DIV(P)(\_U) instruction can be used for division of 16-bit binary data.

## /P)(\_U)

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

These instructions divide the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the result in the device specified by (d).

| Ladder diagram                                                                    | Structured text <sup>*1</sup>                             |                                                               |

## Processing details

- These instructions divide the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the division result in the device specified by (d).

(d): Quotient

(d)+1: Remainder

- For the division result, 32-bit is used for word device to store the quotient and remainder and 16-bit is used for bit device to store quotient only.
- Quotient..... Stored in the lower 16 bits.
- Remainder..... Stored in the upper 16 bits. (This data can be stored for word device only.)

## Processing details

- These instructions divide the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the division result in the device specified by (d).

(d): Quotient

(d)+1: Remainder

- Two devices in total starting from the one specified by (d) are used to store the division result. Make sure that these two devices are not used for another control.
- Quotient..... Stored in the lower 16 bits.
- Remainder..... Stored in the upper 16 bits.

## Related flag

| Device | Name  | Description                                                                                   |
|--------|-------|-----------------------------------------------------------------------------------------------|
| SM700  | Carry | When the operation result of the signed operation exceeds 32767, the carry flag is turned ON. |
| SM8304 | Zero  | When the operation result is 0, the zero flag is turned ON.                                   |
| SM8306 | Carry | When the operation result of the signed operation exceeds 32767, the carry flag is turned ON. |

## Precautions

### Operation result

- The most significant bit of the quotient and remainder indicates the sign (positive: 0, negative: 1), respectively.
- The quotient is negative when either (s1) or (s2) is negative. The remainder is negative when the (s1) is negative.

### Device specified by (d)

- The remainder is not obtained when a bit device is specified with digit specification.

## Program example

## Operation error

| Error code (SD0/SD8067) | Description                                                                              |
|-------------------------|------------------------------------------------------------------------------------------|
| 2820H                   | The device range specified by (d) exceeds the corresponding device range.                |
| 3400H                   | 0 is specified for (s2) value.                                                           |
| 3403H                   | The data type of the data setting is signed data and the operation result exceeds 32767. |

# Multiplying 32-bit binary data

D\*(P)(\_U) instruction and DMUL(P)(\_U) instruction can be used for multiplication of 32-bit binary data.

## D\*(P)(\_U)

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

These instructions multiply the 32-bit binary data in the device specified by (s1) and the 32-bit binary data in the device specified by (s2), and store the result in the device specified by (d).

| Ladder diagram                                                                    | Structured text*1                                         |                                                               |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------|---------------------------------------------------------------|

## Processing details

- These instructions multiply the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the multiplication result in the device specified by (d).

- When (d) is a bit device, only the lower 32 bits of the multiplication result are stored and the upper 32 bits cannot be specified. If the upper 32 bits data of the multiplication operation result are required, temporarily store the result in a word device, and transfer the data stored in word device ((d)+2) and ((d)+3) to the specified bit devices.

### Ex.

Multiplication result when (d) is a bit device

- K1 ... Lower 4 bits (b0 to b3)
- K4 ... Lower 16 bits (b0 to b15)
- K8 ... Lower 32 bits (b0 to b31)

## Operation error

| (s1)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | — | ○           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions multiply the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the multiplication result in the device specified by (d).

- When nibble is specified ranging from K1 to K8 for (d), the result is obtained only for the lower-order 32 bits, and is not obtained for the higher-order 32 bits. Transfer the data to word devices once, then execute the operation.

## Related flag

| Device | Name | Description                                                 |
|--------|------|-------------------------------------------------------------|
| SM8304 | Zero | When the operation result is 0, the zero flag is turned ON. |

## Precautions

- Even if word devices are used, the operation result (64 bits binary data) cannot be monitored at one time. In such a case, a floating point operation is recommended.

## Program example

## Operation error

| Error code (SD0/SD8067) | Description                                                               |
|-------------------------|---------------------------------------------------------------------------|
| 2820H                   | The device range specified by (d) exceeds the corresponding device range. |

# Dividing 32-bit binary data

D/(P)(\_U) instruction and DDIV(P)(\_U) instruction can be used for division of 32-bit binary data.

## D/(P)(\_U)

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

These instructions divide the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the result in the device specified by (d).

| Ladder diagram                                                                    | Structured text*1                                           |                                                                 |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------|-----------------------------------------------------------------|
|  | ENO:=DDIVISION(EN,s1,s2,d);<br>ENO:=DDIVISIONP(EN,s1,s2,d); | ENO:=DDIVISION_U(EN,s1,s2,d);<br>ENO:=DDIVISIONP_U(EN,s1,s2,d); |
| FBD/LD                                                                            |                                                             |                                                                 |

("DDIVISION", "DDIVISIONP", "DDIVISION\_U", "DDIVISIONP\_U" enters □.)

\*1 Supported by engineering tool version "1.035M" and later.

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description         | Range                      | Data type              | Data type (label)                      |
|---------|---------------------|----------------------------|------------------------|----------------------------------------|
| (s1)    | D/(P)               | -2147483648 to +2147483647 | 32-bit signed binary   | ANY32_S                                |
|         | D/(P)_U             | 0 to 4294967295            | 32-bit unsigned binary | ANY32_U                                |
| (s2)    | D/(P)               | -2147483648 to +2147483647 | 32-bit signed binary   | ANY32_S                                |

| (s1)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | —     | — | ○           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions divide the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the division result in the device specified by (d).

- For the division result of word device, 64-bit binary is used to store the quotient and remainder. For bit device, 32-bit binary is used to store quotient only.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| 2820H                      | The device range specified by (d) exceeds the corresponding device range. |
| 3400H                      | 0 is specified for (s2) value.                                            |

## DDIV(P)(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions divide the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the result in the device specified by (d).

| Ladder diagram                                                                    | Structured text                                   |                                                       |

| (s1)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (s2)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | — | ○           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions divide the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the division result in the device specified by (d).

#### ■ Related flag

| Device | Name  | Description                                                                                   |
|--------|-------|-----------------------------------------------------------------------------------------------|
| SM700  | Carry | When the operation result of the signed operation exceeds 32767, the carry flag is turned ON. |
| SM8304 | Zero  | When the operation result is 0, the zero flag is turned ON.                                   |
| SM8306 | Carry | When the operation result of the signed operation exceeds 32767, the carry flag is turned ON. |

## Precautions

### ■Operation result

- The most significant bit of the quotient and remainder indicates the sign (positive: 0, negative: 1), respectively.
- The quotient is negative when either (s1) or (s2) is negative. The remainder is negative when the (s1) is negative.

### ■Device specified by (d)

- The remainder is not obtained when a bit device is specified with digit specification.

## Program example

## Operation error

## Processing details

- These instructions add the BCD 8-digit data in the device specified by (s1) and the BCD 8-digit data in the device specified by (s2), and store the addition result in the device specified by (d).

| (d)+1, (s1)+1, (s2)+1 | (d), (s1), (s2) |
|-----------------------|-----------------|
| Upper 4 digits        | Lower 4 digits  |

- If the addition result exceeds 99999999, carry is ignored. In this case, the carry flag (SM700) does not turn ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------|

## Processing details

- These instructions divide the BCD 4-digit data specified by (s1) by the BCD 4-digit data specified by (s2), and store the results of division in the device specified by (d).

(d): Quotient

(d)+1: Remainder

- The results of division are stored as quotient and remainder using 32 bit(s).
  - Quotient (BCD 4-digit): Stored in lower 16 bit(s).
  - Remainder (BCD 4-digit): Stored in upper 16 bit(s).
- If (d) is specified by bit device, remainder of division results is not stored.

## Operation error

| (d)     | ○                           | ○                         | —     | — | ○           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions multiply the BCD 8-digit data specified by (s1) and the BCD 8-digit data specified by (s2), and store the multiplication results in the device specified by (d).

- When (d) is a bit device, only the lower 8 nibbles (32 bits) of the multiplication result are stored, and the higher 8 nibbles (32 bits) cannot be specified.

### Ex.

Multiplication result when (d) is a bit device

- K1 ... Lower 1 nibble (b0 to b3)
- K4 ... Lower 4 nibble (b0 to b15)
- K8 ... Lower 8 nibble (b0 to b31)

## Processing details

- These instructions divide the BCD 8-digit data specified by (s1) by the BCD 8-digit data specified by (s2), and store the results of division in the device specified by (d).

| (d)+1, (d)+3   | (d), (d)+2     |
|----------------|----------------|
| Upper 4 digits | Lower 4 digits |

- The results of division are stored as quotient and remainder using 64 bit(s) binary.
- Quotient (BCD 8-digit): Stored in lower 32 bit(s).
- Remainder (BCD 8-digit): Stored in upper 32 bit(s).
- If (d) is specified by bit device, remainder of division results is not stored.

## Operation error

| (s2)    | —                           | ○                         | —     | — | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions add (n) point(s) of 16-bit binary data from the device specified by (s1) and the (n) point(s) of 16-bit binary data from the device specified by (s2), and store the results of addition in the device specified by (d).
- Block addition is performed in units of 16-bits.

### Ex.

If device is specified for (s2) (signed)

If constant is specified for (s2) (signed)

- If an underflow or overflow occurs for operation result, the result will be as follows. In this case, the carry flag (SM700) does not turn ON.

| If signed is specified                                                                                                                                                                                                                                                                                                                                                                                   | If unsigned is specified                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\begin{array}{l} \text{K32767} \\ (7\text{FFFH}) \end{array} + \begin{array}{l} \text{K2} \\ (0002\text{H}) \end{array} \Rightarrow \begin{array}{l} \text{K-32767} \\ (8001\text{H}) \end{array}$ $\begin{array}{l} \text{K-32767} \\ (8001\text{H}) \end{array} + \begin{array}{l} \text{K-2} \\ (\text{FFFEH}) \end{array} \Rightarrow \begin{array}{l} \text{K32767} \\ (7\text{FFFH}) \end{array}$ | $\begin{array}{l} \text{K65535} \\ (\text{FFFFH}) \end{array} + \begin{array}{l} \text{K1} \\ (0001\text{H}) \end{array} \Rightarrow \begin{array}{l} \text{K0} \\ (0000\text{H}) \end{array}$ |

## Program example

In the program shown below, the specified number of data stored in D150 to D0 are added to the specified number of data stored in D100 to D0 when X20 is set to ON, and the operation result is stored in D200 and later.

## Operation error

## Processing details

- These instructions subtract (n) point(s) of 16-bit binary data from the device specified by (s1) and the (n) point(s) of 16-bit binary data from the device specified by (s2), and store the subtraction results in the device specified by (d).
- Block subtraction is performed in 16-bit units.

### Ex.

If device has been specified for (s2)

If constant is specified for (s2)

- If an underflow or overflow occurs for operation result, the result will be as follows. In this case, the carry flag (SM700) does not turn ON.

| If signed is specified |   |                | If unsigned is specified |                    |               |
|------------------------|---|----------------|--------------------------|--------------------|---------------|
| K-32767<br>(8001H)     | - | K2<br>(0002H)  | →                        | K32766<br>(7FFE H) |               |
| K32767<br>(7FFFH)      | - | K-2<br>(FFFEH) | →                        | K-32767<br>(8001H) |               |
|                        |   |                | K0<br>(0000H)            | -                  | K1<br>(0001H) |
|                        |   |                | →                        | K65535<br>(FFFFH)  |               |

## Program example

In the program shown below, the constant "K8765" is subtracted from the data stored in D100 to D102 when X10 is set to ON, and the operation result is stored in D200 to D202.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                           |

## Processing details

- These instructions add (n) point(s) of 32-bit binary data from the device specified by (s1) and the (n) point(s) of 32-bit binary data from the device specified by (s2), and store the results of addition in the device specified by (d).
- Block addition is performed in 32-bit units.

**Ex.**

If device is specified for (s2) (signed)

If constant is specified for (s2) (signed)

- Operation is enabled when (s1) or (s2) have been specified by same device as (d) (perfect match). An error occurs if the device range of (n) point(s) from (s1) or (s2) partially matches (overlaps) the device range of (n) point(s) from (d).

**Ex.**

If 4 points of the device from (s2) and (d) match

(1) Because it is a perfect match, operation is possible.

If 4 points of the device from (s2), (d) match partially

(1) An operation error occurs if they partially match.

- If the value specified for (n) is 0, processing is not performed.
- If an underflow or overflow occurs for operation result, the result will be as follows. In this case, the carry flag (SM700) does not turn ON.

| If signed is specified                                                                                                                     | If unsigned is specified                                  |
|--------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| K2147483647 (7FFFFFFH) + K2 (00000002H) → K-2147483647 (80000001H)<br>K-2147483647 (80000001H) + K-2 (FFFFFFFEH) → K2147483647 (7FFFFFFFH) | K4294967295 (FFFFFFFFH) + K1 (00000001H) → K0 (00000000H) |

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                    |

### Processing details

- These instructions subtract (n) point(s) of 32-bit binary data from the device specified by (s1) and the (n) point(s) of 32-bit binary data from the device specified by (s2), and store the results of subtraction in the device specified by (d).
- Block subtraction is performed in 32-bit units.

**Ex.**

If device is specified for (s2) (signed)

If constant is specified for (s2) (signed)

- Operation is enabled when (s1) or (s2) have been specified by same device as (d) (perfect match). An error occurs if the device range of (n) point(s) from (s1) or (s2) partially matches (overlaps) the device range of (n) point(s) from (d).

**Ex.**

If 4 points of the device from (s2) and (d) match

(1)Because it is a perfect match, operation is possible.

If 4 points of the device from (s2), (d) match partially

(1)An operation error occurs if they partially match.

- If the value specified for (n) is 0, processing is not performed.
- If an underflow or overflow occurs for operation result, the result will be as follows. In this case, the carry flag (SM700) does not turn ON.

| If signed is specified      |                               | If unsigned is specified |                              |

## Setting data

### ■ Descriptions, ranges, and data types

| Operand | Description         | Range            | Data type              | Data type (label) |
|---------|---------------------|------------------|------------------------|-------------------|
| (d)     | INC(P)              | -32768 to +32767 | 16-bit signed binary   | ANY16_S           |
|         | INC(P)_U            | 0 to 65535       | 16-bit unsigned binary | ANY16_U           |
| EN      | Execution condition | —                | Bit                    | BOOL              |
| ENO     | Execution result    | —                | Bit                    | BOOL              |

### ■ Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions add 1 to the device (16-bit binary data) specified by (d).

- If INC(P) instruction is executed when contents of device specified by (d) is 32767, -32768 is stored in the device specified by (d). (If signed is specified)
- If INC(P)\_U instruction is executed when contents of device specified by (d) is 65535, 0 is stored in the device specified by (d). (If unsigned is specified)
- Flags (zero, carry and borrow) are not activated at this time.

## Precautions

Note that data is incremented in every operation cycle in a continuous operation type (INC) instruction.

## Program example

Z0 is cleared by the reset input X10.

The current values of counters C0 to C9 are converted into BCD format, and output to K4Y0.

Every time X11 is set to ON, the current values of C0, C1 ... C9 are output one at a time.

## Operation error

There is no operation error.

## Decrementing 16-bit binary data

### DEC(P)(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions subtract 1 from the device (16-bit binary data) specified by (d).

## Processing details

- These instructions exclusive OR each bit of 16-bit binary data from the device specified by (d) and each bit of 16-bit binary data from device specified by (s), and store the results in the device specified by (d).

- Bit devices subsequent to number of points by digit specification are calculated as 0.
- By combining WXOR and CML instructions, the exclusive logical sum not (XORNOT) operation can be executed as well as the WXNR instruction.

## Operation error

There is no operation error.

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions take bit data at position specified by (s2) from device specified by (s1) and write to bit device specified by (d).

(1): (s2) bit (When (s2)=5)

- If relevant bit is "0", device specified by (d) is turned OFF, and if it is "1", device is turned ON.
- For (s2) specify the bit position (0 to 15) of word data. If 16 or more is specified for (s2), the value of the remainder of  $(s2) \div 16$  is the bit position.

### Ex.

For (s2) = 18, the remainder for  $18 \div 16$  is "2", so it becomes data of b2.

## Operation error

There is no operation error.

# Performing a 32-bit test

## DTEST(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions take bit data at position specified by (s2) from device specified by (s1) and write to bit device specified by (d).

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                | Range | Data type                | Data type (label) |
|---------|--------------------------------------------|-------|--------------------------|-------------------|
| (d1)    | Head bit or word device number to be reset | —     | Bit/16-bit signed binary | ANY_ELEMENTARY*1  |
| (d2)    | Last bit or word device number to be reset | —     | Bit/16-bit signed binary | ANY_ELEMENTARY*1  |
| EN      | Execution condition                        | —     | Bit                      | BOOL              |
| ENO     | Execution result                           | —     | Bit                      | BOOL              |

\*1 Digit specified bit type label cannot be used.

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (d1)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | —        | — | —  | —      |
| (d2)    | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions reset all data among devices of same type specified by (d1) and (d2).
- OFF (reset) is written to the entire range of devices from (d1) to (d2) all at once if (d1) and/or (d2) are bit devices.

- K0 is written to the entire range of devices from (d1) to (d2) all at once if (d1) and/or (d2) are word devices.

- As a reset instruction for individual devices, the RST instruction can be used for bit devices and word devices.

- (1): M0 is reset.  
 (2): The current value of T0 is reset.  
 (3): D0 is reset.

- The FMOV(P) instruction is a batch write instruction for a constant (K0 for example) that can write "0" for word devices (including digit specification of bit devices).

- (1): K0 is written to D0 to D99.

## Precautions

- Specify the same type of device for (d1) and (d2) so that (d1) number is less than (d2) number. If the (d1) number  $\geq$  (d2) number, only the device specified by (d1) is reset.
- The ZRST(P) instruction is a 16-bit instruction, but long counter (LC) and long index register (LZ) can be specified for (d1) and (d2).

## Program example

In the program shown below, when the power to the CPU module is turned ON or when the PLC mode is changed to RUN, the specified ranges of bit devices and word devices are reset at one time.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------|
| 2820H                      | The number of devices to be reset is 32768 or more when module access device has been specified for (d1) and/or (d2). |
| 3405H                      | Device type specified by (d1) differs from type specified by (d2).                                                    |
|                            | Module number for (d1) and (d2) differ when module access device is specified.                                        |

# 7.5 Data Conversion Instructions

## Converting binary data to BCD 4-digit data

### BCD(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions convert the binary data in the device specified by (s) to BCD data, and store the converted data in the device specified by (d).

Binary data is used in operations in CPU module. Use this instruction to display numeric values on seven-segment display unit equipped with BCD decoder.

| Ladder diagram                                                                    | Structured text                         |
|-----------------------------------------------------------------------------------|-----------------------------------------|
|  | ENO:=BCD(EN,s,d);<br>ENO:=BCDP(EN,s,d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                    | Range     | Data type            | Data type (label) |
|---------|----------------------------------------------------------------|-----------|----------------------|-------------------|
| (s)     | Binary data or the head device where the binary data is stored | 0 to 9999 | 16-bit signed binary | ANY16             |
| (d)     | Head device for storing the BCD data                           | —         | BCD 4-digit          | ANY16             |
| EN      | Execution condition                                            | —         | Bit                  | BOOL              |
| ENO     | Execution result                                               | —         | Bit                  | BOOL              |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions convert the 16-bit binary data (0 to 9999) in the device specified by (s) to BCD 4-digit data, and store the converted data in the device specified by (d).

(1): Set 0s.

- Data specified by (s) can be converted if it is within the range from K0 to K9999 BCD (decimal).

- The table below shows digit specification for the data in the device specified by (s) and (d).

| (d)  | Number of digits | Data range   |
|------|------------------|--------------|
| K1Y0 | 1-digit          | 0 to 9       |
| K2Y0 | 2-digit          | 00 to 99     |
| K3Y0 | 3-digit          | 000 to 999   |
| K4Y0 | 4-digit          | 0000 to 9999 |

### Precautions

- Binary data is used in all operations in CPU module including arithmetic operations (+, -, ×, ÷), increment and decrement instructions. When receiving digital switch information in binary-coded decimal (BCD) format into a CPU module, use the BIN(P) instructions (for converting BCD data into binary data). Furthermore, to output data to seven-segment display unit handling binary-coded decimal (BCD) data, use the BCD(P) instructions (for converting binary data into BCD data).

### Program example

- When the seven-segment display unit has 1-digit

- When the seven-segment display unit has 2 to 4-digits

### Operation error

| Error code<br>(SD0/SD8067) | Description                                                                |
|----------------------------|----------------------------------------------------------------------------|
| 3401H                      | Data in the device specified by (s) is out of the valid range (0 to 9999). |

# Converting binary data to BCD 8-digit data

## DBCD(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions convert the binary data in the device specified by (s) to BCD data, and store the converted data in the device specified by (d).

Binary data is used in operations in CPU module. Use this instruction to display numeric values on seven-segment display unit equipped with BCD decoder.

| Ladder diagram                                                                    | Structured text                                   |

|  | <pre>ENO:=DBCD(EN,s,d); ENO:=DBCDP(EN,s,d);</pre> |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                    | Range         | Data type            | Data type (label) |
|---------|----------------------------------------------------------------|---------------|----------------------|-------------------|
| (s)     | Binary data or the head device where the binary data is stored | 0 to 99999999 | 32-bit signed binary | ANY32             |
| (d)     | Head device for storing the BCD data                           | —             | BCD 8-digit          | ANY32             |
| EN      | Execution condition                                            | —             | Bit                  | BOOL              |
| ENO     | Execution result                                               | —             | Bit                  | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions convert 32-bit binary data (0 to 99999999) in device specified by (s) to BCD 8-digit data, and store the converted data in the device specified by (d).

(1): Set 0s to the upper 5 bits.

- Data specified by (s) can be converted if it is within the range from K0 to K99999999 BCD (decimal).

- The table below shows digit specification for the data in the device specified by (s) and (d).

| (d)+1, (d) | Number of digits | Data range           |
|------------|------------------|----------------------|
| K1Y0       | 1-digit          | 0 to 9               |
| K2Y0       | 2-digit          | 00 to 99             |
| K3Y0       | 3-digit          | 000 to 999           |
| K4Y0       | 4-digit          | 0000 to 9999         |
| K5Y0       | 5-digit          | 00000 to 99999       |
| K6Y0       | 6-digit          | 000000 to 999999     |
| K7Y0       | 7-digit          | 0000000 to 9999999   |
| K8Y0       | 8-digit          | 00000000 to 99999999 |

### Precautions

- Binary data is used in all operations in CPU module including arithmetic operations (+, -, ×, ÷), increment and decrement instructions. When receiving digital switch information in binary-coded decimal (BCD) format into a CPU module, use the BIN(P) instructions (for converting BCD data into binary data). Furthermore, to output data to seven-segment display unit handling binary-coded decimal (BCD) data, use the BCD(P) instructions (for converting binary data into BCD data).

### Program example

- When the seven-segment display unit has 5 to 8-digits

### Operation error

| Error code (SD0/SD8067) | Description                                                                    |
|-------------------------|--------------------------------------------------------------------------------|
| 3401H                   | Data in the device specified by (s) is out of the valid range (0 to 99999999). |

# Converting BCD 4-digit data to binary data

## BIN(P)

FX5S    FX5UJ    FX5U    FX5UC

These instructions convert the binary-coded decimal data in the device specified by (s) to binary data, and store the converted data in the device specified by (d).

Use this instruction to convert a binary-coded decimal (BCD) value such as a value set by a digital switch into binary (BIN) data and to receive the converted binary data so that the data can be handled in operations in CPU module.

| Ladder diagram                                                                    | Structured text                         |
|-----------------------------------------------------------------------------------|-----------------------------------------|
|  | ENO:=BIN(EN,s,d);<br>ENO:=BINP(EN,s,d); |

## Processing details

- These instructions convert the BCD 4-digit data (0 to 9999) in the device specified by (s) to 16-bit binary data, and store the converted data in the device specified by (d).

(1): Filled with 0s.

- The data in the device specified by (s) can be converted if it is in the range from 0 to 9999 (BCD).

- The table below shows digit specification for the data in the device specified by (s) and (d).

| (d)  | Number of digits | Data range   |
|------|------------------|--------------|
| K1X0 | 1-digit          | 0 to 9       |
| K2X0 | 2-digit          | 00 to 99     |
| K3X0 | 3-digit          | 000 to 999   |
| K4X0 | 4-digit          | 0000 to 9999 |

### Precautions

- Binary data is used in all operations in CPU module including arithmetic operations (+-×÷), increment and decrement instructions. When receiving digital switch information in binary-coded decimal (BCD) format into a CPU module, use the BIN(P) instructions (for converting BCD data into binary data). Furthermore, to output data to seven-segment display unit handling binary-coded decimal (BCD) data, use the BCD(P) instructions (for converting binary data into BCD data).

### Program example

- When the digital switch has 1-digit

- When the digital switch has 2 to 4-digits

### Operation error

| Error code (SD0/SD8067) | Description                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------|
| 3401H                   | The value of each digit of the device specified by (s) is other than 0 to 9. (The data is not binary-coded decimal data.) |

# Converting BCD 8-digit data to binary data

## DBIN(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions convert the binary-coded decimal data in the device specified by (s) to binary data, and store the converted data in the device specified by (d).

Use this instruction to convert a binary-coded decimal (BCD) value such as a value set by a digital switch into binary (BIN) data and to receive the converted binary data so that the data can be handled in operations in CPU module.

| Ladder diagram                                                                    | Structured text                                   |

## Processing details

- These instructions convert the BCD 8-digit data (0 to 99999999) in the device specified by (s) to 32-bit binary data, and store the converted data in the device specified by (d).

- The data in the device specified by (s) can be converted if it is in the range from 0 to 99999999 (BCD).

- The table below shows digit specification for the data in the device specified by (s) and (d).

| (s)+1, (s) | Number of digits | Data range           |
|------------|------------------|----------------------|
| K1X0       | 1-digit          | 0 to 9               |
| K2X0       | 2-digit          | 00 to 99             |
| K3X0       | 3-digit          | 000 to 999           |
| K4X0       | 4-digit          | 0000 to 9999         |
| K5X0       | 5-digit          | 00000 to 99999       |
| K6X0       | 6-digit          | 000000 to 999999     |
| K7X0       | 7-digit          | 0000000 to 9999999   |
| K8X0       | 8-digit          | 00000000 to 99999999 |

## Precautions

- Binary data is used in all operations in CPU module including arithmetic operations (+-x÷), increment and decrement instructions. When receiving digital switch information in binary-coded decimal (BCD) format into a CPU module, use the BIN instruction (for converting BCD data into binary data). Furthermore, to output data to seven-segment display unit handling binary-coded decimal (BCD) data, use the BCD instruction (for converting binary data into BCD data).

## Program example

- When the digital switch has 5 to 8-digits

## Processing details

- These instructions convert the 32-bit binary gray code data in the device specified by (s) to 32-bit binary data, and store the converted data in the device specified by (d).

## Precautions

When an input relay (X) is specified as (s), the response delay will be "Scan time of CPU module + Input filter constant".

## Operation error

There is no operation error.

# Converting decimal ASCII to 16-bit binary data

## DABIN(P)(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions convert the decimal ASCII data in the device areas specified by (s) and later to 16-bit binary data, and store the converted data in the device specified by (d).

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions convert the decimal ASCII data in the device areas specified by (s) and later to 16-bit binary data, and store the converted data in the device specified by (d).
- The setting method of the decimal ASCII data to be set in (s) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705*1 | Setting method of (s)                                                                     | Reference                                                                                    |
|-------------------|-------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| OFF               | Set (s) with a fixed number of digits (a sign + 5 digits in the numeric part).            | Page 353 Setting method of (s) for when SM705 (Number of conversion digits selection) is off |
| ON                | Set (s) with a desired number of digits (maximum: a sign + 5 digits in the numeric part). | Page 354 Setting method of (s) for when SM705 (Number of conversion digits selection) is on  |

\*1 For the firmware version of the CPU module supporting SM705, refer to the following.

MELSEC iQ-F FX5 User's Manual (Application)

A CPU module which does not support SM705 operates in the same way as SM705 is off even if it is turned on.

■Setting method of (s) for when SM705 (Number of conversion digits selection) is off

Set decimal ASCII data with the fixed number of digits in (s) to (s)+2.

ASCII S: ASCII code for sign  
 ASCII 10<sup>0</sup>: ASCII code for the ones place  
 ASCII 10<sup>1</sup>: ASCII code for the tens place  
 ASCII 10<sup>2</sup>: ASCII code for the hundreds place  
 ASCII 10<sup>3</sup>: ASCII code for the thousands place  
 ASCII 10<sup>4</sup>: ASCII code for the ten-thousands place

- The ASCII data in the device specified by (s) to (s)+2 is within the range from -32768 to 32767 when signed data is specified, and it is within the range from 0 to 65535 when unsigned data is specified.
- The data of (s)+3 or later is ignored.
- As sign data, set 20H (space) when the ASCII data is positive, and set 2DH (-) when the data is negative. (If a value other than 20H and 2DH is set, the data will be processed as positive data.)
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H or 00H is set in each place of ASCII code, the value will be processed as 30H.

**Ex.**

When the ASCII data, -25108 (signed), is specified by (s)

## ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set decimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set if the integral part has the maximum number of digits (5 digits).

The following table lists the setting method of (s).

| Value to be set in (s)                                                                                 | Data of (s) to (s)+2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Value to be set in (s) | Data of (s) to (s)+2            |       |     |    |     |                       |  |                       |  |       |                       |  |                       |  |       |                       |  |                       |  |                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |     |     |       |     |    |     |                       |  |                                 |  |       |                       |  |                       |  |       |  |  |                       |  |

- The ASCII data in the device specified by (s) to (s)+2 is within the range from -32768 to 32767 when signed data is specified, and it is within the range from 0 to 65535 when unsigned data is specified.
- Set 2DH (-) to lower byte of (s)+0 as sign data when the ASCII data is negative. Set an ASCII code of the uppermost digit instead of setting sign data when the ASCII data is 0 or positive.
- A value from 30H to 39H can be set in each place of ASCII code.
- If the value is positive and the numeric part has 5 digits, the data of the upper byte of (s)+2 or later is ignored. If the value is negative and the numeric part has 5 digits, the data of (s)+3 or later is ignored.
- If a value 20H is set in each place of ASCII code, the value is processed as 30H. If a value 00H is set, the value is processed as the end of the decimal ASCII data.
- In the following cases, 0 is stored.
  - The first character is 00H (NULL).
  - The first character is 2DH (-) and the second character is 00H (NULL).

## Program example

In the program below, the signed decimal ASCII codes in five digits stored in D20 to D22 are converted into 16-bit binary data and stored in D0 when X0 is set to ON.

## Operation error

|                            | A value specified by (s) to (s)+2 for each place of the ASCII code is other than "30H" to "39H", "20H", and "00H".                     |
|                            | The ASCII data in the device specified by (s) to (s)+2 is out of the valid range (-32768 to +32767) (when a signed data is specified). |
|                            | The ASCII data in the device specified by (s) to (s)+2 is out of the valid range (0 to 65535) (when unsigned data is specified).       |

\*<sup>1</sup> This error occurs when SM705 is on. When SM705 is off, sign data other than "2DH (-)" is ignored.

# Converting decimal ASCII to 32-bit binary data

## DDABIN(P)(\_U)

FX5S

FX5UJ

FX5U

FX5UC

These instructions convert the decimal ASCII data in the device numbers specified by (s) and later to 32-bit binary data, and store the converted data in the device specified by (d).

## Processing details

- These instructions convert the decimal ASCII data in the device numbers specified by (s) and later to 32-bit binary data, and store the converted data in the device specified by (d).
- The setting method of the decimal ASCII data to be set in (s) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 <sup>*1</sup> | Setting method of (s)                                                                      | Reference                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| OFF                           | Set (s) with a fixed number of digits (a sign + 10 digits in the numeric part).            | Page 357 Setting method of (s) for when SM705 (Number of conversion digits selection) is off |
| ON                            | Set (s) with a desired number of digits (maximum: a sign + 10 digits in the numeric part). | Page 358 Setting method of (s) for when SM705 (Number of conversion digits selection) is on  |

<sup>\*1</sup> For the firmware version of the CPU module supporting SM705, refer to the following.

MELSEC iQ-F FX5 User's Manual (Application)

A CPU module which does not support SM705 operates in the same way as SM705 is off even if it is turned on.

### ■Setting method of (s) for when SM705 (Number of conversion digits selection) is off

Set decimal ASCII data with the fixed number of digits in (s) to (s)+5.

ASCII S: ASCII code for sign

ASCII 10<sup>0</sup>: ASCII code for the ones place

ASCII 10<sup>1</sup>: ASCII code for the tens place

ASCII 10<sup>2</sup>: ASCII code for the hundreds place

ASCII 10<sup>3</sup>: ASCII code for the thousands place

ASCII 10<sup>4</sup>: ASCII code for the ten-thousands place

ASCII 10<sup>5</sup>: ASCII code for the hundred-thousands place

ASCII 10<sup>6</sup>: ASCII code for the millions place

ASCII 10<sup>7</sup>: ASCII code for the ten-millions place

ASCII 10<sup>8</sup>: ASCII code for the hundred-millions place

ASCII 10<sup>9</sup>: ASCII code for the billions place

(1): Ignore

(2): Upper 16 bits

(3): Lower 16 bits

- The ASCII data in the device specified by (s) to (s)+5 is within the range from -2147483648 to +2147483647 when signed data is specified, and it is within the range from 0 to 4294967295 when unsigned data is specified. Any data stored in the upper byte of the device specified by (s)+5 is ignored.
- As sign data, set 20H if the ASCII data is positive, and set 2DH if the data is negative. (If a value other than 20H and 2DH is set, the data will be processed as positive data.)
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H or 00H is set in each place of ASCII code, the value will be processed as 30H.

#### Ex.

When the ASCII data, -1234543210 (signed), is specified by (s)

## ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set decimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set if the integral part has the maximum number of digits (10 digits).

The following table lists the setting method of (s).

| Value to be set in (s)                                                                                                                          | Data of (s) to (s)+5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Value to be set in (s) | Data of (s) to (s)+5            |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |  |  |  |  |  |                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |     |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |  |  |                       |  |  |

⋮

ASCII 10<sup>9</sup>: ASCII code for the billions place

- The ASCII data in the device specified by (s) to (s)+5 is within the range from -2147483648 to 2147483647 when signed data is specified, and it is within the range from 0 to 4294967295 when unsigned data is specified.
- Set 2DH (-) to lower byte of (s)+0 as sign data when the ASCII data is negative. Set an ASCII code of the uppermost digit instead of setting sign data when the ASCII data is 0 or positive.
- A value from 30H to 39H can be set in each place of ASCII code.
- If the value is positive and the numeric part has 10 digits, the data stored in (s)+5 or later is ignored. If the value is negative and the numeric part has 10 digits, the data stored in the upper byte of (s)+5 or later is ignored.
- If a value 20H is set in each place of ASCII code, the value is processed as 30H. If a value 00H is set, the value is processed as the end of the decimal ASCII data.
- In the following cases, "0" is stored in (d).
  - The first character is 00H (NULL).
  - The first character is 2DH (-) and the second character is 00H (NULL).

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H                      | The device specified by (s) exceeds the corresponding device range.                                                                              |
| 3401H                      | The sign data is other than 20H, 2DH.* <sup>1</sup>                                                                                              |
|                            | A value specified by (s) to (s)+2 for each place of the ASCII code is other than "30H" to "39H", "20H", and "00H".                               |
|                            | The ASCII data in the device specified by (s) to (s)+5 is out of the valid range (-2147483648 to +2147483647) (when a signed data is specified). |
|                            | The ASCII data in the device specified by (s) to (s)+5 is out of the valid range (0 to 4294967295) (when unsigned data is specified).            |

\*<sup>1</sup> This error occurs when SM705 is on. When SM705 is off, sign data other than "2DH (-)" is ignored.

# Converting ASCII to HEX

## HEXA(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions convert the ASCII data stored in the number of characters specified by (n) in the device numbers specified by (s) and later to HEX code data, and store the converted data in the device numbers specified by (d) and later.

## Processing details

These instructions convert the ASCII data stored in the number of characters specified by (n) in the device numbers specified by (s) and later to HEX code data, and store the converted data in the device numbers specified by (d) and later. 16-bit conversion mode and 8-bit conversion mode options are available for these instructions. For operation in each mode, refer to the succeeding pages.

- 16-bit conversion mode (while SM8161 is OFF)

The ASCII data stored in high-order 8 bits and low-order 8 bits (byte) of the device specified by (s) is converted to hexadecimal code, and transferred to the device specified by (d) in units of 4 digits. The number of characters to be converted is specified by (n).

SM8161 is also used for the ASCI(P), CRC(P), and CCD(P) instructions. When using the 16-bit conversion mode, set SM8161 to normally OFF.

SM8161 is cleared when the CPU module mode is changed from RUN to STOP.

Moreover, when using the 16-bit conversion mode, the ASCII data must also be stored in high-order 8 bits of the device specified by (s).

In the following program, conversion is executed as follows:

(1): 16-bit conversion mode

Conversion source data

| (s)             | ASCII data | Hexadecimal code |
|-----------------|------------|------------------|
| D200 low-order  | 30H        | 0                |

(1): The data remain the same.

- 8-bit conversion mode (while SM8161 is on)

The ASCII data stored in low-order 8 bits of the device specified by (s) is converted to hexadecimal code, and transferred to the device specified by (d) in units of 4 digits.

The number of characters to be converted is specified by (n).

SM8161 is also used for the ASCI(P), CRC(P), and CCD(P) instructions. When using the 8-bit conversion mode, set SM8161 to normally on.

SM8161 is cleared when the CPU module mode is changed from RUN to STOP.

In the following program, conversion is executed as follows:

Conversion source data

| (s)  | ASCII data | Hexadecimal code |
|------|------------|------------------|
| D200 | 30H        | 0                |
| D201 | 41H        | A                |

(1): The data remain the same.

### Precautions

- Make sure that only ASCII codes "0" to "9" and "A" to "F" are stored in the device specified by (s).
- If ASCII data is not stored in the device specified for (s) by the HEXA(P) instructions, an operation error occurs and conversion into hexadecimal code is disabled. Especially, note that when SM8161 is OFF (16-bit conversion mode), ASCII code should be stored in high-order 8 bits of the device specified by (s).
- The number of points occupied by the device specified by (d) varies depending on the ON/OFF status of SM8161. When SM8161 is on (8-bit conversion mode), as many points as the number of characters are occupied, and when SM8161 is OFF (16-bit conversion mode) as many points as the (number of characters ÷2) are occupied.
- The SM8161 flag is also used for the ASCI(P), CRC(P), and CCD(P) instructions. When using these instructions and the HEXA(P) instructions in the same program, make sure to set SM8161 to ON or OFF just before each instruction so that SM8161 does not affect another instruction.

### Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------|
| 2820H                      | The (n) number of devices specified by (s) and (d) exceeds the corresponding device range. |
| 2821H                      | The range specified by (s) and (d) overlaps.                                               |
| 3401H                      | An ASCII code other than 30H to 39H, and 41H to 46H is set in the device specified by (s). |
| 3405H                      | The value specified in (n) is outside the range specified below.<br>1 to 16383             |

# Converting character string to 16-bit binary data

## VAL(P)(\_U)

FX5S

FX5UJ

\*1 T, ST, and C cannot be used.

## Processing details

- These instructions convert the character string in the device numbers specified by (s) and later to 16-bit binary data, and store the number of digits in the device specified by (d1) and the binary data in the device specified by (d2). When converting a character string into binary data, the data from the device number specified by (s) to a device number storing "00H" is handled as a character string.
- The total number of digits stored in (d1) is the total number of characters (including the sign and decimal point) representing the numeric value. The number of digits in the decimal part stored in (d1)+1 is the number of characters representing the decimal part after 2EH (.). The 16-bit binary data stored in (d2) is binary value converted from a character string with the decimal point ignored.

### Ex.

When the character string "-123.45" (signed) is specified by (s) and later

- The total number of characters of the character string specified by (s) is 2 to 8 characters.
- In the character string specified by (s), the number of characters that form the decimal part is 0 to 5 characters. However, be sure to specify "Total number of digits - 3" or below.
- The range of the character string of the numeric value that can be converted to a binary value is -32768 to +32767 for a signed value with the decimal point ignored, and 0 to 65535 for an unsigned value. A character string of a numeric value excluding the sign and decimal point can be specified only within the range of 30H to 39H. (Value with the decimal point ignored ... "-12345.6" becomes "-123456".)
- When representing a positive numeric value, 20H is set in the sign, and when representing a negative numeric value, 2DH is set.
- 2EH is set in the decimal point.
- When "20H (space)" or "30H (0)" exists between the sign and the first non-zero number in a character string specified by (s), "20H" or "30H" is ignored during conversion to a binary value.

### Ex.

When "20H" exists between the sign and the first non-zero number (a signed value is specified)

### Ex.

When "30H" exists between the sign and the first non-zero number

- Do not set 2EH(.) to the last character of (s). (Example: 1234.)

## Precautions

- Store signed data, "space (20H)" or "-" (2DH)" only in the 1st byte (low-order 8 bits of the head device set in (s)). Only the ASCII data "0 (30H)" to "9 (39H)", "space (20H)" and "decimal point (2EH)" can be stored from the 2nd byte to the "00H" at the end of the character string in (s). If "-" (2DH)" is stored in the 2nd byte or later, an operation error occurs.

## Program example

In the program below, the character string data stored in D20 to D22 is regarded as an integer value. This value is converted into a binary value, and stored in D0 when X0 is set to ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Processing details

- These instructions convert the character string in the device numbers specified by (s) and later to 32-bit binary data, and store the number of digits in the device specified by (d1) and the binary data in the device specified by (d2). When converting a character string into binary data, the data from the device number specified by (s) to a device number storing "00H" is handled as a character string.

- The total number of digits stored in (d1) is the total number of characters (including the sign and decimal point) representing the numeric value. The number of digits in the decimal part stored in (d1)+1 is the number of characters representing the decimal part after 2EH (.). The 32-bit binary data stored in (d2) is binary value converted from a character string with the decimal point ignored.

#### Ex.

When the character string "-12345.678" (signed) is specified by (s) and later

- The total number of characters of the character string specified by (s) is 2 to 13 characters.
- In the character string specified by (s), the number of characters that form the decimal part is 0 to 10 characters. However, be sure to specify "Total number of digits - 3" or below.
- The range of the character string of the numeric value that can be converted to a binary value is -2147483648 to 2147483647 for a signed value with the decimal point ignored, and 0 to 4294967295 for an unsigned value. A character string of a numeric value excluding the sign and decimal point can be specified only within the range of 30H to 39H. (Value with the decimal point ignored ... "-12345.6" becomes "-123456".)
- When representing a positive numeric value, 20H is set in the sign, and when representing a negative numeric value, 2DH is set.
- Set 2EH in the decimal point.
- The total number of digits stored in (d1) includes all characters (including signs and decimal points) that represent a numerical value. The number of digits in the decimal part stored in (d1)+1 is the number of characters representing the decimal part after 2EH (.). The binary data to be stored in (d2) is the binary value converted from the character string with the decimal point ignored.
- When "20H (space)" or "30H (0)" exists between the sign and the first non-zero number in a character string specified by (s), "20H" or "30H" is ignored during conversion to a binary value.

**Ex.**

When "20H" exists between the sign and the first non-zero number (a signed value is specified)

**Ex.**

When "30H" exists between the sign and the first non-zero number

- Do not set 2EH(.) to the last character of (s). (Example: 1234.)

## Precautions

- Store sign data, "space (20H)" or "-" (2DH)" in the 1st byte (low-order 8 bits of the head device set in (s)). Only the ASCII data "0 (30H)" to "9 (39H)", "space (20H)" and "decimal point (2EH)" can be stored from the 2nd byte to the "00H" at the end of the character string in (s). If "-" (2DH)" is stored in the 2nd byte or later, an operation error occurs.

## Program example

In the program below, the character string data stored in D20 to D24 is regarded as an integer value. This value is converted into 32-bit binary data, and stored in D0 and D1 when X0 is set to ON.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Precautions

Note that data is inverted in every operation cycle in a continuous operation type (NEG) instruction.

## Program example

The program examples below are provided to obtain the absolute value of a negative binary 16-bit data.

- Obtaining the absolute value of a negative value using NEG instruction

- Obtaining the absolute value by SUB (subtraction) instruction

Even if NEG instruction is not used, D30 always stores the absolute value of the difference.

## Operation error

There is no operation error.

# Two's complement of 32-bit binary data (sign inversion)

## DNEG(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions invert the sign of the 32-bit binary data in the device specified by (d), and store the resultant data in the device specified by (d).

\*1 Digit specified bit device cannot be used.

\*2 Bit-specified word device cannot be used.

### Processing details

- These instructions turn ON the bit position of the device specified by (d) in correspondence to the BIN value specified by the lower-order (n) bits of (s).

- When (n) is 0, no processing is performed, and the contents of the device specified by (d) do not change.
- The bit device is handled as a device storing one-bit data and the word device is handled as a device storing 16-bit data.

## Program example

- When setting bit devices to ON according to the value of a data register

The value of D0 (whose current value is "14" in this example) is decoded to M0 to M15.

- When the value of b0 to b3 of D0 is "14" ( $= 0 + 2 + 4 + 8$ ), M14 (which is the 15th from M0) becomes "1" (turn ON).
- When the value of D0 is "0", M0 becomes "1" (turns ON).
- When "n" is set to "K4", either one point among M0 to M15 turns ON according to the value of D0 (0 to 15).
- By changing "n" from K1 to K8, D0 can correspond to numeric values from 0 to 255. However, because the device range of (d) is occupied for decoding accordingly, such device range should not be used for another control.

- Turning ON the bit out of word devices according to the contents of bit devices

The value expressed by X0 to X2 is decoded to D0 (X0 and X1 are ON, and X2 is OFF in this example.).

- When the values expressed by X0 to X2 are "3" ( $= 1 + 2 + 0$ ), b3 (which is the 4th from b0) becomes 1 (turns ON).
- When all of X0 to X2 are "0" (OFF), b0 becomes "1" (turns ON).

## Operation error

| Error code (SD0/SD8067) | Description                                                         |

# Seven-segment decoding

## SEGD(P)

- FX5S
- FX5UJ
- FX5U
- FX5UC

This instruction decodes data, and turns the seven-segment display unit (1 digit) ON.

| Ladder diagram                                                                    | Structured text                           |

\*1 X cannot be used.

## Processing details

- "0" to "F" (hexadecimal numbers) in low-order 4 bits (1 digit) of (s) are decoded to data for the seven-segment display unit, and stored in the low-order 8 bits of (d). Low-order 8 bits of (d) are occupied, and high-order 8 bits do not change.
- Seven-segment decode table is as follows.

| (s)         |    |    |    |    | Seven-segment<br>data<br>components                                               | (d) |    |    |    |    |    |    |    |    |    |    |   | Display<br>data |

## Operation error

There is no operation error.

# Seven Segment With Latch

## SEGL

FX5S    FX5UJ    FX5U    FX5UC

This instruction controls one or two sets of 4-digit seven-segment display units having the latch function.

\*1 Only Y can be used.

## Processing details

The 4-digit numeric value stored in (s) is converted into BCD data, and each digit is output to the seven-segment display unit with the BCD decoder by the time division method. For (s), binary data ranging from 0 to 9999 is valid.

Set the parameters (n) as follows according to the positive/negative logic of the PLC and the positive/negative logic of the seven-segment display module.

| PLC output logic | Data input                | Strobe signal             | Parameter "n"    |                  |
|------------------|---------------------------|---------------------------|------------------|------------------|
|                  |                           |                           | 4 digits × 1 set | 4 digits × 2 set |
| Negative logic   | Negative logic (match)    | Negative logic (match)    | 0                | 4                |
|                  |                           | Positive logic (mismatch) | 1                | 5                |
|                  | Positive logic (mismatch) | Negative logic (match)    | 2                | 6                |
|                  |                           | Positive logic (mismatch) | 3                | 7                |
| Positive logic   | Positive logic (match)    | Negative logic (mismatch) | 0                | 4                |
|                  |                           | Positive logic (match)    | 1                | 5                |
|                  | Negative logic (mismatch) | Negative logic (mismatch) | 2                | 6                |
|                  |                           | Positive logic (match)    | 3                | 7                |

### ■When using one set of 4 digits (n = K0 to K3)

A 4-digit numeric value stored in (s) is converted from binary into BCD, and each digit is output in turn from (d) to (d)+3 by the time division method. The strobe signal is output in turn from (d)+4 to (d)+7 by the time division method also to latch one set of 4-digit seven-segment display unit.

### ■When using two sets of 4 digits (n = K4 to K7)

#### 1st set of 4 digits

A 4-digit numeric value stored in (s) is converted from binary into BCD, and its each digit is output in turn from (d) to (d)+3 by the time division method. The strobe signal is output in turn from (d)+4 to (d)+7 by the time division method also to latch the first set of 4-digit seven-segment display unit.

#### 2nd set of 4 digits

A 4-digit numeric value stored in (s)+1 is converted from binary into BCD, and its each digit is output in turn from (d)+10 to (d)+13 by the time division method. The strobe signal is output in turn from (d)+4 to (d)+7 by the time division method also to latch the second set of 4-digit seven-segment display unit.

For the connection example of two seven-segment display units, refer to the following manual.

📖 MELSEC iQ-F FX5S/FX5UJ/FX5U/FX5UC User's Manual (Hardware)

## Precautions

- The scan time (operation cycle) multiplied by 12 is required to update (one or two sets of) the 4-digit display.
- While the command input is ON, the operation is repeated. When the command contact is set to OFF in the middle of an operation, the operation is paused. When the command contact is set to ON again, the operation is started from the beginning.
- When one set of 4 digits is used, one device is occupied from the device specified in (s) and eight devices are occupied from the device specified in (d).
- When two sets of 4 digits are used, two devices are occupied from the device specified in (s) and twelve devices are occupied from the device specified in (d).
- SEGL instruction is executed in synchronization with the scan time (operation cycle) of the CPU module. For achieving a series of display, the scan time of the CPU module should be 10 ms or more. If the scan time is less than 10 ms, the display may be incorrect. (If the scan time is less than 10 ms, use the constant scan mode so that the scan time is 10 ms or more.)
- Use a transistor output type CPU module.
- The SEGL instruction can only be executed four times in a program.
- When a constant (K or H) is specified as (s), operate as shown below.  
When one set of 4 digits is used: It operates considering the constant specified by (s) as the 1st set.  
When two sets of 4 digits are used: It operates considering the constant specified by (s) as the 1st set, and the 2nd set fixed to 0.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                     |
|----------------------------|---------------------------------------------------------------------------------|
| 2820H                      | The device specified by (s) or (d) exceeds the corresponding device range.      |
| 3405H                      | (n) is other than 0 to 7.                                                       |
|                            | The value specified by (s), (s)+1 is other than 0 to 9999.                      |
| 1811H                      | The number of the SEGL instructions which are used simultaneously exceeds four. |

# Separating 4 bits from 16-bit data

## DIS(P)

FX5S    FX5UJ    FX5U    FX5UC

These instructions store the data equivalent of the (n) nibbles (1-nibble/ 4-bits) of the 16-bit binary data specified by (s) in to the lower-order 4 bits of (n) number of devices starting from the one specified by (d).

## Processing details

- These instructions store the data equivalent of the (n) nibbles (1-nibble/ 4-bits) of the 16-bit binary data specified by (s) in to the lower-order 4 bits of (n) number of devices starting from the one specified by (d).

(1): Data storage area

- The higher-order 12 bits of (n) number of devices starting from the one specified by (s) becomes 0.
- When (n) is 0, no processing is performed, and the contents of the (n) number of devices starting from the one specified by (d) do not change.

## Program example

In the program below, D0 is separated into 4 bit units and stored in D10 to D13 when X0 turns ON.

## Operation error

## Processing details

- These instructions separate each bit of the data in the device numbers specified by (s1) and later into bit units specified by (s2), and store the separated data in the device numbers starting from the one specified by (d).

(s2) to (s2)+6: Number of bits specified by (s2) to (s2)+6

(1): The value 0 indicates the end of setting.

- The number of separation bits specified by (s2) can be specified within the range of 1 to 16 bits.
- The number of bits specified in devices from the device number specified by (s2) up to the device number in which "0" is stored are processed as the number of separation bits.
- If the device numbers specified by (s1), (s2), (d) are partially overlapping, an operation error occurs.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                |

| 2820H                      | The usage range of the device specified by (s1) or (d) exceeds the corresponding device range due to the specification of the number of link bits specified by (s2). |
| 2821H                      | The (s1), (s2) devices are overlapping.                                                                                                                              |
|                            | The (s1), (d) devices are overlapping.                                                                                                                               |
|                            | The (s2), (d) devices are overlapping.                                                                                                                               |
| 3401H                      | The specification of the number of link bits specified by (s2) is not set within the range of 1 to 16 bits.                                                          |
|                            | 0 is not set in the range between the device specified by (s2) up to the corresponding device range.                                                                 |

# Separating data in byte units

## WTOB(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions separate the 16-bit binary data in the device numbers starting from the one specified by (s) onwards into (n) byte units, and store the separated data in the device number specified by (d) onwards.

| Ladder diagram | Structured text                                       |
|----------------|-------------------------------------------------------|
|                | <pre>ENO:=WTOB(EN,s,n,d); ENO:=WTOBP(EN,s,n,d);</pre> |
| FBD/LD         |                                                       |
|                |                                                       |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                   | Range      | Data type              | Data type (label) |
|---------|---------------------------------------------------------------|------------|------------------------|-------------------|
| (s)     | Head device where the separation target data is stored        | —          | 16-bit signed binary   | ANY16             |
| (d)     | Head device for storing the result of separation in byte unit | —          | 16-bit signed binary   | ANY16             |
| (n)     | Number of byte units                                          | 0 to 65535 | 16-bit unsigned binary | ANY16             |
| EN      | Execution condition                                           | —          | Bit                    | BOOL              |
| ENO     | Execution result                                              | —          | Bit                    | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions separate the 16-bit binary data in the device numbers starting from the one specified by (s) onwards into (n) byte units, and store the separated data in the device number specified by (d) onwards.

- (1): Upper byte  
 (2): Lower byte  
 (3): Upper byte data  
 (4): Lower byte data

\*1 Values after the decimal point are rounded up.

### Ex.

For example, when (n) is 5, data starting from (s) to the lower 8 bits of (s)+2 is stored into (d) through (d)+4.

(1): The data FEH is ignored when (n) is 5.

(2): When (n) is 5

- Setting the number of bytes by (n) automatically determines the 16-bit binary data range specified by (s) and the device range specified by (d) for storing the separated byte data.
- If (n) is 0, no processing is performed.
- In the upper 8 bits of the devices specified by (d) to hold byte data, 00H is automatically stored.

### Ex.

To store data in D12 to D14 into the lower 8 bits of D11 to D16

(1): 00H is automatically stored.

- Even if the device range of the data to be separated and the device range for storing the separated data overlap, the processing is performed normally.

| Device range where the data to be separated is stored | Device range for storing the separated data |
|-------------------------------------------------------|---------------------------------------------|
| (s) to (s)+(n/2 - 1)                                  | (d)+0 to (d)+(n)-1                          |

## Program example

In the program shown below, the data stored in D10 to D12 is separated in byte units, and stored in D20 to D25 when X0 is set to ON.

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 2820H                   | The range of no. of bytes specified in (n) from the device number specified in (s) onwards exceed the corresponding device range. |
|                         | The range of (n) points of devices from the device number specified in (d) onwards exceed the corresponding device range.         |

## Connecting data in byte units

### BTOW(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions link the lower-order 8 bits of the 16-bit binary data of (n) number of bytes stored in the device numbers starting from the one specified by (s) onwards into word units, and store the linked data in the device numbers starting from the one specified by (d) onwards.

| Ladder diagram | Structured text                                       |
|----------------|-------------------------------------------------------|
|                | <pre>ENO:=BTOW(EN,s,n,d); ENO:=BTOWP(EN,s,n,d);</pre> |
| FBD/LD         |                                                       |
|                |                                                       |

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                    | Range      | Data type              | Data type (label) |
|---------|----------------------------------------------------------------|------------|------------------------|-------------------|
| (s)     | Head device for storing the data to be linked in byte units    | —          | 16-bit signed binary   | ANY16             |
| (d)     | Head device storing data acquired by combination in byte units | —          | 16-bit signed binary   | ANY16             |
| (n)     | Number of byte data to be linked                               | 0 to 65535 | 16-bit unsigned binary | ANY16             |
| EN      | Execution condition                                            | —          | Bit                    | BOOL              |
| ENO     | Execution result                                               | —          | Bit                    | BOOL              |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                           | ○                         | —     | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions link the lower-order 8 bits of the 16-bit binary data of (n) number of bytes stored in the device numbers starting from the one specified by (s) onwards into word units, and store the linked data in the device numbers starting from the one specified by (d) onwards.
- The higher-order 8 bits of the data of (n) words stored in device numbers starting from the one specified by (s) are ignored. If (n) is an odd number, 0 is stored in the higher-order 8 bits of the device for storing the data of the (n)th byte.

□: □th byte data

(1): The upper byte data are ignored.

\*1 Values after the decimal point are rounded up.

### Ex.

For example, when (n) is 5, lower 8 bits of data from (s) through (s+4) is stored into (d) through (d)+2.

(1): When (n) is 5

(2): Filled with 00H.

- Setting the number of bytes by (n) automatically determines the byte data range specified by (s) and the device range specified by (d) for storing the linked data.
- If (n) is 0, no processing is performed.
- The higher-order 8 bits of the device specified by (s) for storing byte data are ignored, and only the lower-order 8 bits are applicable.

### Ex.

To store data in lower 8 bits of D11 to D16 into D12 to D14

- Even if the device range of the data to be linked and the device range for storing the linked data overlap, the processing is performed normally.

| Device range where the data to be linked is stored | Device range for storing the linked data |
|----------------------------------------------------|------------------------------------------|
| (s)+0 to (s)+(n)-1                                 | (d) to (d)+( $\frac{n}{2}-1$ )           |

## Program example

In the program shown below, the low-order 8-bits data stored in D20 to D25 is combined, and stored in D10 to D12 when X0 is set to ON.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 2820H                      | The range of (n) points of devices from the device number specified in (s) onwards exceed the corresponding device range.         |
|                            | The range of no. of bytes specified in (n) from the device number specified in (d) onwards exceed the corresponding device range. |

# 7.6 Digital Switch

## DSW

FX5S

FX5UJ

FX5U

FX5UC

This instruction reads the set value of digital switches. This instruction can read a set of 4 digits (n = K1) or two sets of 4 digits (n = K2).

| (n)     | —                           | —                         | —     | — | —           | —  | —                      | ○        | — | —  | —      |

\*1 Only X can be used.

\*2 Only Y can be used.

## Processing details

The value of each digital switch connected to (s) is input by the time division method (in which the value is input in turn from the 1st digit by 100 ms interval output signal), and stored to (d2). A numeric value from 0 to 9999 (up to 4 digits) can be read, the first set is stored to (d2), and the second set is stored to (d2)+1.

### When using one set of 4 digits (n = K1)

A 4-digit BCD digital switch connected to (s) to (s)+3 is read in turn by the strobe signal (d1) to (d1)+3, and stored in binary format to (d2).

### When using two sets of 4 digits (n = K2)

A 4-digit BCD digital switch connected to (s) to (s)+7 is read in turn by the strobe signal (d1) to (d1)+3. (s) to (s)+3 is stored in (d2) and (s)+4 to (s)+7 is stored in (d2)+1 as BIN format.

For the connection example of digital switch, refer to the following manual.

 MELSEC iQ-F FX5S/FX5UJ/FX5U/FX5UC User's Manual (Hardware)

## Precautions

- Though the contents of (d2) do not change, all of (d1) to (d1)+3 turn OFF.
- When one set of 4 digits (n = K1) are used, four devices are occupied starting from (s).
- When two sets of 4 digits (n = K2) are used, eight devices are occupied starting from (s), and two devices are occupied starting from (d2).
- When connecting a digital switch of less than 4 digits, it is not necessary to wire the strobe signal (output for digit specification) (d1) to unused digits. Because unused digits are occupied also by this instruction, however, they cannot be used for any other purpose.
- For continuously receiving digital switch values, make sure to use a transistor output type CPU module.
- Use BCD output type digital switches.
- The DSW instruction can only be executed four times in a program.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                           |
|----------------------------|---------------------------------------------------------------------------------------|
| 3405H                      | (n) is other than 1 or 2.                                                             |
|                            | The value specified by (s) to (s)+3 and (s)+4 to (s)+7 is other than 0 to 9.          |
| 2820H                      | The device range specified by (s), (d1), (d2) exceeds the corresponding device range. |
| 1811H                      | The number of the DSW instructions which are used simultaneously exceeds four.        |

# 7.7 Data Transfer Instructions

## Transferring 16-bit data

### MOV(P)

FX5S FX5UJ FX5U FX5UC

These instructions transfer the 16-bit binary data in the device specified by (s) to the device specified by (d).

| Ladder diagram                                                                    | Structured text                         |
|-----------------------------------------------------------------------------------|-----------------------------------------|
|  | ENO:=MOV(EN,s,d);<br>ENO:=MOVP(EN,s,d); |
| FBD/LD                                                                            |                                         |
|  |                                         |

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                            | Range            | Data type            | Data type (label) |
|---------|--------------------------------------------------------|------------------|----------------------|-------------------|
| (s)     | Transfer source data or device number for storing data | -32768 to +32767 | 16-bit signed binary | ANY16             |
| (d)     | Transfer destination device number                     | —                | 16-bit signed binary | ANY16             |

| (s)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions transfer the 16-bit binary data in the device specified by (s) to the device specified by (d).

## Program example

- When reading the current value of a timer and counter

- When indirectly specifying the set value of a timer or counter

As the set value of the timer T20, two values can be specified by turning ON or OFF the switch X2.

For specifying more than two set values, more than one switch is required.

- When transferring a bit device

The following sequence program can be programmed by using MOV instruction.

## Operation error

There is no operation error.

# Transferring 32-bit data

## DMOV(P)

FX5S FX5UJ FX5U FX5UC

These instructions transfer the 32-bit binary data in the device specified by (s) to the device specified by (d).

| (s)     | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions transfer the 32-bit binary data in the device specified by (s) to the device specified by (d).

## Program example

Make sure to use DMOV instruction for transferring an instruction (such as MUL instruction) whose operation result is output in 32 bits, a 32-bit numeric value or a 32-bit device.

## Operation error

There is no operation error.

## Inverting and transferring 16-bit data

### CML(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions invert each bit of the 16-bit binary data in the device specified by (s), and transfer the result to the device specified by (d).

| Ladder diagram | Structured text                                 |
|----------------|-------------------------------------------------|
|                | <pre>ENO:=CML(EN,s,d); ENO:=CMLP(EN,s,d);</pre> |
| FBD/LD         |                                                 |
|                |                                                 |

### Setting data

#### ■ Descriptions, ranges, and data types

| Operand | Description                                                  | Range            | Data type            | Data type (label) |
|---------|--------------------------------------------------------------|------------------|----------------------|-------------------|
| (s)     | Data to be inverted or device number in which data is stored | -32768 to +32767 | 16-bit signed binary | ANY16             |
| (d)     | Device number for storing the inversion result               | —                | 16-bit signed binary | ANY16             |

| ENO     | Execution result                                             | —                | Bit                  | BOOL              |

#### ■ Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions invert each bit of the 16-bit binary data in the device specified by (s), and transfer the result to the device specified by (d).

## Program example

- When receiving an inverted input

The sequence program shown below can be written by CML instruction.

- When four bits are specified for a device with digit specification

## Operation error

There is no operation error.

## Inverting and transferring 32-bit data

### DCML(P)

FX5S

FX5UJ

FX5U

FX5UC

These instructions invert each bit of the 32-bit binary data in the device specified by (s), and transfer the result to the device specified by (d).

| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |
| (n3)    | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

These instructions distribute and compose data in units of nibble (4 bits). The contents of the transfer source (s) and transfer destination (d) are converted into 4-digit BCD (0000 to 9999). (n2) nibbles starting from the (n1)th nibble are transferred to the transfer destination (d) starting from the (n3)th nibble, converted into binary, and then stored to the transfer destination (d).

- While the command input is OFF, the transfer destination (d) does not change.
- When the command input turns ON, only the specified digits in the transfer destination (d) are changed. The transfer source (s) and unspecified digits in the transfer destination (d) do not change.

## Extension function

When SM8168 is set to ON first and then SMOV instruction is executed, conversion from binary to BCD is not executed. Data is moved in units of 4 bits.

## Program example

The data on three-digit digital switches are composed, and stored as binary data to D2.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                   |
|----------------------------|---------------------------------------------------------------|
| 3405H                      | Any one of (n1), (n2), (n3) is 0.                             |
|                            | Either (s) or (d) is other than 0 to 9999 when SM8168 is OFF. |
|                            | Either (n1) or (n3) is larger than 4.                         |
|                            | (n2) is larger than (n1) or (n3).                             |

# Inverting and transferring 1-bit data

## CMLB(P)

FX5S    FX5UJ    FX5U    FX5UC

These instructions invert the bit data in the device specified by (s), and transfer the result into the device specified by (d).

## Processing details

- These instructions block transfer the 16-bit binary data of (n) number of devices starting from the one specified by (s) to the device specified by (d).

- If the device number range is exceeded, data is transferred within the possible range.
- Data can be transferred even when the device range of the transfer-source device and transfer-destination device is overlapping. To transfer data to a device having a smaller device number, transfer from (s), and to transfer data to a device having a larger device number, transfer from (s)+(n)-1.

### Ex.

When transferring data to a device having a smaller device number

When transferring data to a device having a larger device number

## Precautions

- To perform digit specification of bit device for both (s) and (d), be sure to set the same number of nibbles for (s) and (d).

- To use a module access device for (s) and (d), specify either (s) or (d).

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------|
| 3405H                      | The number of nibbles of the digit specification of bit device of (s) and (d) is different. |
| 3420H                      | A module access device is specified for both (s) and (d).                                   |

# Transferring identical 16-bit block data (65535 points maximum)

## FMOV(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions transfer (n) point(s) of data identical to the 16-bit binary data in the device specified by (s) to the device specified by (d).

### Processing details

- These instructions transfer (n) point(s) of data identical to the 16-bit binary data in the device specified by (s) to the device specified by (d).

- If the number of points specified by (n) exceeds the device number range, data is transferred within the possible range.
- When a constant (K) is specified as the transfer source (s), it is automatically converted into binary.

## Precautions

When the value specified in (n) is 0, an operation error does not occur, but no processing is performed.

## Program example

- When writing specified data to two or more devices

## Operation error

There is no operation error.

### Processing details

These instructions exchange 32-bit binary data of (d1), (d1)+1 and (d2), (d2)+1

## Program example

This program exchanges the contents of D0, D1 and D2, D3 when X2 is set to ON.

## Operation error

There is no operation error.

# Exchanging the upper and lower bytes of 16-bit data

## SWAP(P)

**FX5S** **FX5UJ** **FX5U** **FX5UC**

These instructions swap the value of 8 bits of the upper and lower bytes of the device specified by (d).

**Ladder diagram**

**Structured text**

## Processing details

### ■ROR(P)

- These instructions rotate the 16-bit binary data in the device specified by (d) to the right by (n) bit(s) (not including the carry flag). The carry flag is on or off depending on the status prior to the execution of the instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 15 and the specified number of bits is 12, 3 bits are rotated because 15 divided by 12 equals 1 with a remainder of 3.
- Specify any value between 0 and 15 for (n). If a value 16 or bigger is specified, bits are rotated by the remainder value of  $n \div 16$ . For example, when (n) is 18, 2 bits are rotated because 18 divided by 16 equals 1 with a remainder of 2.

### ■RCR(P)

- These instructions rotate the 16-bit binary data in the device specified by (d) to the right by (n) bit(s) (including the carry flag). The carry flag is on or off depending on the status prior to the execution of the instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 15 and the specified number of bits is 12, 3 bits are rotated because 15 divided by 12 equals 1 with a remainder of 3.
- Specify any value between 0 and 15 for (n). If a value 16 or bigger is specified, bits are rotated by the remainder value of  $n \div 16$ . For example, when (n) is 18, 2 bits are rotated because 18 divided by 16 equals 1 with a remainder of 2.

## Precautions

- Do not set a negative value to the number of bits to be rotated (n).
- In the case of continuous operation type instructions (ROR and RCR), note that shift and rotation are executed in every scan time (operation cycle).

## Operation error

There is no operation error.

# Rotating 16-bit data to the left

## ROL(P), RCL(P)

**FX5S**

**FX5UJ**

**FX5U**

**FX5UC**

- ROL(P): These instructions rotate the 16-bit binary data in the device specified by (d) to the left by (n) bit(s) (not including the carry flag).
- RCL(P): These instructions rotate the 16-bit binary data in the device specified by (d) to the left by (n) bit(s) (including the carry flag).

| Ladder diagram                                                                    | Structured text <sup>*1</sup>                                      |

## Processing details

### ■DROR(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the right by (n) bit(s) (not including the carry flag). The carry flag is on or off depending on the status prior to the execution of the instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of (n)÷(specified number of bits). For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of n÷32. For example, when (n) is 34, 2 bits are rotated because 34 divided by 32 equals 1 with a remainder of 2.

## ■DRCR(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the right by (n) bit(s) (including the carry flag). The carry flag is on or off depending on the status prior to the execution of the instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of  $n \div 32$ . For example, when (n) is 34, 2 bits are rotated because 34 divided by 32 equals 1 with a remainder of 2.

## Precautions

- Do not set a negative value to the number of bits to be rotated (n).
- In the case of continuous operation type instructions (DROR and DRCR), note that shift and rotation are executed in every scan time (operation cycle).

## Operation error

There is no operation error.

## Processing details

### ■DROL(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the left by (n) bit(s) (not including the carry flag). The carry flag is on or off depending on the status prior to the execution of the instruction.

- When (d) is a bit device, bits are rotated to the left within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of (n)÷(specified number of bits). For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of n÷32. For example, when (n) is 34, 2 bits are rotated because 34 divided by 32 equals 1 with a remainder of 2.

## ■DRCL(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the left by (n) bit(s) (including the carry flag). The carry flag is on or off depending on the status prior to the execution of the instruction.

- When (d) is a bit device, bits are rotated to the left within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of  $n \div 32$ . For example, when (n) is 34, 2 bits are rotated because 34 divided by 32 equals 1 with a remainder of 2.

## Precautions

- Do not set a negative value to the number of bits to be rotated (n).
- In the case of continuous operation type instructions (DROL and DRCL), note that shift and rotation are executed in every scan time (operation cycle).

## Operation error

There is no operation error.

## 8.2 Program Branch Instruction

### Pointer branch

#### CJ(P)

**FX5S****FX5UJ****FX5U****FX5UC**

These instructions execute the program specified by the pointer number within the same program file when the jump command is on.

#### Processing details

#### ■CJ(P)

- These instructions execute the program specified by the pointer number when the execution command is on.
- When the execution command is off, the program in the next step is executed.

- (1): Execution command  
(2): Executed in each scan  
(3): One Scan

#### Precautions

- If the timer with its coil on is skipped by these instructions, time cannot be measured correctly.
- If the OUT instruction is skipped by these instructions, the scan time will be shortened.
- If these instructions specify and jump to a later step, the scan time will be shortened.

- These instructions can specify and jump from the current step to a smaller step number. In this case, consider a method to exit a loop so that the watchdog timer does not time out.

- (1) While X3 is on, the loop is repeated.  
(2) To exit the loop, turn on Y5.

- The value in the device skipped with these instructions remains the same.

When X2 turns on, the program jumps to the label, P19.  
Y4 and Y5 remain the same even if X2 and X4 turn on/off during the execution of the CJ instruction.

- A label (P□) occupies two steps.

- (1) A label occupies two steps.

- Only the pointer numbers within the same program file can be specified.
- During skip operation, if the program jumps to the pointer number within the skip range, the programs of the jump destination pointer number and later are executed.
- The figure below shows programming of a label. When creating a circuit program, move the cursor to the left side of the bus line in the ladder diagram, and input a label (P) at the head of the circuit block.

- (1): Bus line  
(2): Label

- A label can be programmed in a smaller number step than CJ instruction. However, note that a watchdog timer error occurs when the scan time exceeds 200 ms (default setting).

- When the pointer number in operands is same and there is one label, the following operation is caused:

- (1) When X20 turns ON, the program execution jumps from CJ instruction corresponding to X20 to the label P9.
- (2) When X20 turns OFF and X21 turns ON, the program execution jumps from CJ instruction corresponding to X21 to the label P9.

- When a label number (including labels for CALL instructions described later) is used two or more times, an error is caused.

A: User program

- No label can be shared by CALL instruction and CJ instruction.

A: User program

- (1): Subroutine program dedicated to CALL instruction
- (2): Program a label (P) after FEND instruction.

- Because SM400/SM8000 is normally ON while the CPU module is operating, unconditional jump is applied when SM400/SM8000 is used as shown in the following example:

A\*: User program (It is skipped, and is not executed.)

A: User program

- In one operation cycle after X23 changes from OFF to ON, the CJ instruction becomes valid. By using this method, jump can be executed after all outputs between the CJ instruction and the label P7 turn OFF.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                          |
|----------------------------|--------------------------------------------------------------------------------------|

# Jump to END

## GOEND

- FX5S
- FX5UJ
- FX5U
- FX5UC

This instruction moves the program execution to the FEND or END instruction in the same program file.

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | Not supported   |

| FBD/LD         |
|----------------|
| Not supported. |

### Processing details

- This instruction moves the program execution to the FEND or END instruction in the same program file.

### Precautions

- When a GOEND instruction is executed by invalid jump during interrupt program execution, it becomes the same operation as the IRET instruction.

### Operation error

| Error code (SD0/SD8067) | Description                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 3340H                   | After the FOR instruction is executed, the GOEND instruction is executed before the NEXT instruction is executed.             |
| 3381H                   | After the CALL(P) or XCALL instruction is executed, the GOEND instruction is executed before the RET instruction is executed. |

# 8.3 Program Execution Control Instruction

## Disabling/enabling interrupt programs

DI, EI

FX5S FX5UJ FX5U FX5UC

Interrupts are usually disabled in CPU module. These instructions enable interrupts in CPU module (EI instruction) or disable interrupts again (DI instruction).

- DI: Disables the execution of the interrupt program.
- EI: Releases the execution disabled state of interrupt programs.

| Ladder diagram                                                                    | Structured text              |
|-----------------------------------------------------------------------------------|------------------------------|
|  | ENO:=DI(EN);<br>ENO:=EI(EN); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Processing details

#### DI

- This instruction disables the execution of the interrupt program until the EI instruction is executed, even if the interrupt cause occurs.
- When the power is turned on or the CPU module is reset, the state in which the DI instruction is executed is applied.
- For the operation of the DI instruction (DI instruction without an argument) when using the interrupt disable instruction with a specified priority or lower (DI instruction with an argument), refer to  Page 443 Disabling the interrupt program with specified priority or lower.

#### EI

- This instruction releases the execution disabled state of interrupt programs when the DI instruction is executed, and enables the execution of the interrupt program with the interrupt pointer number enabled by the IMASK instruction.
- For the operation of the EI instruction when using the interrupt disable instruction with a specified priority or lower (DI instruction with an argument), refer to  Page 443 Disabling the interrupt program with specified priority or lower.

A: Sequence program  
B: Interrupt Program

Even though an interrupt occurs between the DI and EI instructions, the execution of the interrupt is held until the processing between the instructions ends.

- An interrupt pointer occupies two steps. (In (1) below, I10 is the step 50, X2 is the step 52, and Y10 is the step 54.)

- If the master control contains the EI or DI instruction, such an instruction is executed regardless of the execution of the MC instruction.

## Precautions

Interrupts (requests) that are generated after the DI instruction execution, are processed after the EI instruction is executed.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                      |
|----------------------------|--------------------------------------------------|
| 3362H                      | Nesting of the DI instruction exceeds 16 levels. |

# Disabling the interrupt program with specified priority or lower

## DI

FX5S    FX5UJ    FX5U    FX5UC

This instruction disables the execution of the interrupt program with a priority specified by (s) or lower until the EI instruction is executed, even if the interrupt cause occurs.

**Structured text**

ENO:=DI\_1(EN,s);

**FBD/LD**

("DI\_1" enters □.)

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                       | Range  | Data type              | Data type (label) |
|---------|-----------------------------------|--------|------------------------|-------------------|
| (s)     | Priority for disabling interrupts | 1 to 3 | 16-bit unsigned binary | ANY16             |
| EN      | Execution condition               | —      | Bit                    | BOOL              |
| ENO     | Execution result                  | —      | Bit                    | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- This instruction disables the execution of the interrupt program of the interrupt pointer number with an interrupt priority specified by (s) or lower.

Interrupt priority setting

| I No. | Priority |
|-------|----------|
| I01   | 2        |
| I02   | 3        |

A: Sequence program  
B: Interrupt Program

- (1): Interrupt-disabled section for the priority 3 or lower  
(Interrupt-enabled section for the priority 2 or higher)  
(2): Can be executed because of the priority 2.  
(3): Cannot be executed because of the priority 3.

- By executing the EI instruction, the interrupt with the priority disabled by the counterpart DI instruction is enabled. However, when interrupts are disabled only with the DI instruction without an argument, interrupts with all the priorities are enabled by executing the EI instruction once.

- Interrupts (requests) that are generated after the DI instruction are processed after the EI instruction is executed.
- When multiple DI instructions are executed and the argument has a priority higher than the currently disabled priority, interrupts with a priority lower than that of the argument are disabled.
- When multiple DI instructions are executed and the argument has a priority lower than the currently disabled priority, the interrupt disabled state is not changed.
- The DI instruction can be nested in up to 16 levels.
- The interrupt priority of the interrupt pointer can be set with parameters. (MELSEC iQ-F FX5 User's Manual (Application))
- The interrupt-disabled priority can be checked with SD758 (interrupt-disabling priority setting value).
- The following shows the interrupt-disabled section when the DI or EI instruction is executed.

- When multiple DI instructions are executed (when interrupts with a priority higher than the currently disabled priority are specified and disabled)

- When multiple DI instructions are executed (when interrupts with a priority lower than the currently disabled priority are specified and disabled)

- When the DI instruction is executed in an interrupt program

A: Scan execution type program

B: Interrupt Program

(1): Interrupt-enabled section for all priority

(2): Interrupt-disabled section for the priority 3 or lower (interrupt-enabled section for the priority 2 or higher)

(3): Interrupt-disabled section for the priority 2 or lower (interrupt-enabled section for the priority 1 or higher)

- When the DI instruction without an argument is executed

A: Scan execution type program

(1): Interrupt-enabled section for all priority

(2): Interrupt-disabled section for the priority 1 or lower (where all the interrupts are disabled)

(3): Because interrupts are disabled with the DI instruction without an argument, interrupts with all the priorities are enabled by executing the EI instruction once.

8

- When the DI instructions with and without an argument are executed (Execution order is DI instruction with an argument → DI instruction without an argument)

A: Scan execution type program

(1): Interrupt-enabled section for all priority

(2): Interrupt-disabled section for the priority 2 or lower (interrupt-enabled section for the priority 1 or higher)

(3): Interrupt-disabled section for the priority 1 or lower (where all the interrupts are disabled)

- When the DI instructions with and without an argument are executed (Execution order is DI instruction without an argument → DI instruction with an argument)

A: Scan execution type program

(1): Interrupt-enabled section for all priority

(2): Interrupt-disabled section for the priority 1 or lower (where all the interrupts are disabled)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                       |
|----------------------------|-------------------------------------------------------------------|
| 3405H                      | The value specified by (s) is other than the following.<br>1 to 3 |

## Processing details

- This instruction enables or disables the execution of the interrupt program with the interrupt pointer number specified by (I) according to the data specified by (s)
- When 1 is set in (s): The execution of the interrupt program is enabled.
- When 0 is set in (s): The execution of the interrupt program is disabled.
- When the power is turned on or the CPU module is reset, execution of the interrupt programs is enabled.

■FX5S CPU module

Interrupt program: I0 to I31

■FX5UJ/FX5U/FX5UC CPU module

Interrupt program: I0 to I177

- The execution-enabled/disabled states of interrupt pointers are stored in the IMASK instruction mask pattern.

■FX5S CPU module

IMASK instruction mask pattern: SD1400 to SD1401

■FX5UJ/FX5U/FX5UC CPU module

IMASK instruction mask pattern: SD1400 to SD1411

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------------------|

|                            | The value in (s) is other than the interrupt disabled (0) or interrupt enabled (1).                           |

# Returning from the interrupt program

## IRET

- FX5S
- FX5UJ
- FX5U
- FX5UC

This instruction indicates an end of the processing of an interrupt program.

| Ladder diagram                                                                    | Structured text |
|-----------------------------------------------------------------------------------|-----------------|
|  | Not supported   |

| FBD/LD         |
|----------------|
| Not supported. |

### Processing details

When an interrupt (input or timer) is generated while the main program is executing, the program execution jumps to an interrupt (I) routine. The IRET instruction returns the program execution to the main routine. The table below shows three types of jump to an interrupt routine.

| Function                                  | Interrupt No. | Description                                                                                                            |
|-------------------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------|
| Interrupt from inputs (including counter) | I0 to I23     | Interrupt pointer used for the CPU built-in functions (such as input interrupt, high-speed comparison match interrupt) |
| Interrupt setting from internal timer     | I28 to I31    | Interrupt pointer used for fixed-cycle interrupts of the internal timer                                                |
| Interrupt from module <sup>*1</sup>       | I50 to I177   | Interrupt pointer used with module equipped with interruption function                                                 |

<sup>\*1</sup> FX5S does not support this function.

### Program example

- Parameter setting

When using the input interrupt (detection of rising of X0), the high-speed comparison match interrupt (the high-speed counter CH2 reaches 10) and the internal timer interrupt (20 ms cycle), set interrupt and the high-speed counter by the parameter. [Input interrupt]

Navigation window ⇒ [Parameter] ⇒ Module model name ⇒ [Module Parameter] ⇒ [High Speed I/O] ⇒ "Input Function" ⇒ "General/Interrupt/Pulse Catch" ⇒ "Detailed Setting"

[high-speed comparison match interrupt]

Navigation window ⇒ [Parameter] ⇒ Module model name ⇒ [Module Parameter] ⇒ [High Speed I/O] ⇒ "Input Function"  
⇒ "High Speed Counter" ⇒ "Detailed Setting" ⇒ "Basic Settings"

Navigation window ⇒ [Parameter] ⇒ Module model name ⇒ [Module Parameter] ⇒ [High Speed I/O] ⇒ "Input Function"  
⇒ "High Speed Counter" ⇒ "Detailed Setting" ⇒ "High Speed Compare Table"

[Interrupt Settings from Internal Timer]

The parameter is used in default setting. To change the parameter, set it as follows.

Navigation window ⇒ [Parameter] ⇒ Module model name ⇒ [CPU Parameter] ⇒ "Interrupt Settings" ⇒ "Fixed Scan Interval Setting" ⇒ "Interrupt Setting from Internal Timer"

• Program

Interrupts are usually disabled in CPU modules.  
Turn ON X7 and use EI instruction to enable interrupts.  
When X0 turns ON while the main program is executed, instructions after the input interrupt routine pointer I0 are executed, and the program execution returns to the original main program by IRET instruction.

Make sure to program an interrupt pointer (I\*\*) as a label after FEND instruction.

The high-speed counter interrupt of the pointer I16 is executed when the current value of a high-speed counter becomes equivalent to a value specified by the parameter. The program execution returns to the original main program by IRET instruction.

The timer interrupt of the pointer I30 is executed every timer time of 20 ms, and the program execution is returned to the original main program by IRET instruction each time.

## Operation error

|----------------------------|-------------------------------------------------------|
| 33E6H                      | The IRET instruction is executed in the main program. |

# Resetting the watchdog timer

## WDT(P)

FX5S    FX5UJ    FX5U    FX5UC

These instructions reset the watchdog timer in a program.

| Ladder diagram                                                                    | Structured text                 |
|-----------------------------------------------------------------------------------|---------------------------------|
|  | ENO:=WDT(EN);<br>ENO:=WDTP(EN); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Processing details

- These instructions reset the watchdog timer in a program.
- These instructions are used when the scan time exceeds the value set for the watchdog timer depending on the condition. If the scan time exceeds the value set for the watchdog timer every scan, change the setting of the watchdog timer in the parameter setting of the engineering tool.
- Design a program so that t1 from the step 0 to the WDT(P) instruction and t2 from the WDT(P) instruction to the END (FEND) instruction do not exceed the setting value of the watchdog timer.

- The WDT(P) instruction can be used more than once in one scan. However, note that turning off the output takes some time if an error occurs.

### Precautions

- The time of the watchdog timer can be changed in the [RAS] tab of [CPU Parameter]. The default value is 200 ms.
- By overwriting the contents of SD8000 (watchdog timer time), the watchdog timer detection time can be changed using a program. When the program shown below is input, the sequence program will be monitored with the new watchdog timer time.

(1): Watchdog timer time: 300 ms

(2): Refreshes the watchdog timer.

If the WDT instruction is not programmed, the value of SD8000 is valid during END processing.

### Operation error

There is no operation error.

## 8.4 Structuring Instruction

### FOR to NEXT

#### FOR, NEXT

FX5S

FX5UJ

FX5U

FX5UC

When the processing between the FOR and NEXT instructions is executed (n) times without any condition, the processing of the step following the NEXT instruction is executed.

| Ladder diagram                                                                                                 | Structured text |

#### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                         | Range      | Data type            | Data type (label) |
|---------|---------------------------------------------------------------------|------------|----------------------|-------------------|
| (n)     | Number of repetitions of the loop between FOR and NEXT instructions | 1 to 32767 | 16-bit signed binary | ANY16             |
| EN      | Execution condition                                                 | —          | Bit                  | BOOL              |
| ENO     | Execution result                                                    | —          | Bit                  | BOOL              |

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

#### Processing details

- When the processing between the FOR and NEXT instructions is executed (n) times without any condition, the processing of the step following the NEXT instruction is executed.
- In (n), any of 1 to 32767 can be specified. If any of -32768 to 0 is specified, the processing of (n)=1 is applied.
- To skip the processing between the FOR and NEXT instructions, jump the program execution with the CJ instruction.
- Up to 16 FOR instructions can be nested.

## Precautions

- The FOR-NEXT loop can be nested up to 16 levels.

- The FOR-NEXT loop cannot be interrupted by the I, IRET, SRET, RET, FEND, or END instruction.
- When FOR-NEXT loop is repeated many times, the operation cycle is too long, and a watchdog timer error may occur. In such a case, change the watchdog timer time or reset the watchdog timer.
- The following programs are regarded as errors.

When the NEXT instruction is located before FOR

No NEXT instruction

When the number of FOR instructions is not equivalent to the number of NEXT instructions

When the NEXT instruction is located after the FEND or END instruction

## Program example

- Program with three FOR-NEXT loops

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                              |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------|
| 3340H                      | After the FOR instruction is executed, the END or GOEND instruction is executed before the NEXT instruction is executed. |
| 3361H                      | When the FOR instruction is nested, the 17th level is executed.                                                          |
| 33E3H                      | A program is written where the nesting of the FOR to NEXT instructions exceeds 16 levels.                                |

### Point

- To terminate the FOR to NEXT instruction loop halfway, use the BREAK instruction. (Page 458 Forcibly terminating the FOR to NEXT instruction loop)

# Forcibly terminating the FOR to NEXT instruction loop

## BREAK(P)

FX5S    FX5UJ    FX5U    FX5UC

This instruction forcibly terminates the FOR to NEXT instruction loop and shifts the program execution to the pointer specified by (P).

| (P) <sup>*1</sup> | Pointer number of the branch destination when the loop is forcibly terminated | —     | Device name          | POINTER           |
| EN                | Execution condition                                                           | —     | Bit                  | BOOL              |
| ENO               | Execution result                                                              | —     | Bit                  | BOOL              |

<sup>\*1</sup> In the case of the FBD/LD language, P displays as Pn.

#### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others (P) |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|------------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |            |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —          |
| (P)     | —                           | —                         | —     | — | —           | —  | —                      | —        | — | —  | ○          |

### Processing details

- This instruction forcibly terminates the FOR to NEXT instruction loop and shifts the program execution to the pointer specified by (P). Only the pointer numbers within the same program file can be specified in (P). If a pointer in another program is specified in (P), an operation error occurs.

- In (d), the number of remaining FOR to NEXT instruction loops at the forced termination is stored. Note that the number includes the loop when the BREAK(P) instructions are executed.
- The BREAK(P) instructions can be used only between the FOR and NEXT instructions.

- The BREAK(P) instructions can be used for only one nesting level. To forcibly terminate multiple nesting levels, execute as many BREAK(P) instructions as the number of nesting levels.

## Precautions

- If the branch pointer number of the BREAK instruction outside two nesting levels or more is specified, an operation error occurs and the program execution stops when the BREAK instruction is executed.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                          |

### Processing details

- When the CALL(P) instructions are executed, the subroutine program specified by the pointer (P) is executed. The CALL(P) instructions can execute a subroutine program specified by a pointer in the same program file or by a common pointer.

A: Main routine program  
B: Subroutine program

- While the command input is ON, the CALL instruction is executed and the program execution jumps to a step with a label (Pn). Then, a subroutine program with the label (Pn) is executed. When the RET (SRET) instruction is executed, the program execution returns to the step following the CALL instruction. At the end of the main program, put FEND instruction. Put a label (Pn) for the CALL instruction after the FEND instruction.

- The CALL(P) instructions can be nested up to 16 levels. However, the 16 levels are the total of the CALL(P) and XCALL instructions.

## Precautions

- In the CALL instruction, the same number can be used two or more times in operands (P). However, do not use a label (P) and number used in another instruction (CJ instruction).

A: User program

- In a subroutine (or interrupt routine), use timers for routine programs. These timers count when a coil instruction or END instruction is executed. After a timer reaches the set value, the output contact is activated when the coil instruction or END instruction is executed. Because general timers count only when the coil instruction is executed, they do not count if they are used in subroutines in which the coil instruction is executed only under some conditions.
- If a retentive type 1 ms timer is used in a subroutine (interrupt routine), note that the output contact is activated when the first coil instruction (or subroutine) is executed after the timer reaches its set value.

- Devices which were set to ON in a subroutine (or interrupt routine) are latched in the ON status even after the subroutine is finished. (Refer to the program example shown below). When the RST instruction for a timer or counter is executed, the reset status of the timer or counter is latched also. For turning OFF such a device latched in the ON status or for canceling such a timer or counter latched in the reset status, reset such a device in the main program after the subroutine is finished, or program a sequence for resetting such a device or for deactivating the RST instruction in the subroutine. (Refer to the program example shown below).

#### Example in which outputs are latched

In the following program example, the counter C0 is provided to count X1. When X0 is input, the subroutine P0 is executed only in one scan, and then the counter is reset and Y7 is output.

[Program example]

[Timing chart]

A: Execution of subroutine P0 triggered by X0

- (1): Because the C0 reset instruction is valid, the current value of C0 remains unchanged even if a pulses are input.  
 (2): Outputs are latched.

Example in which latched outputs are reset (countermeasures)

[Program example]

- (1): Program to reset Y7 at an arbitrary timing
- (2): Program to reset the preceding C0 reset instruction inside the subroutine

[Timing chart]

## Program example

- Example of fundamental use (no nesting)

- Example of multiple CALL instructions in subroutines (multiple nesting)

CALL instruction can be used up to 4 times in subroutine programs. Nesting of up to sixteen layers is allowed.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 3360H                      | The 17th level of the nesting is executed.                                                                                                        |
| 3380H                      | The subroutine program specified by the pointer in the CALL(P) instructions do not exist.                                                         |
| 3381H                      | After the CALL(P) instructions are executed, the END, FEND, GOEND, or STOP instruction is executed before the RET (SRET) instruction is executed. |
| 3382H                      | The RET (SRET) instruction is executed before the CALL(P) instructions are executed.                                                              |

# Returning from the subroutine program

## RET/SRET

**FX5S**   **FX5UJ**   **FX5U**   **FX5UC**

These instructions indicate an end of a subroutine program.  
The RET instruction can be used as SRET.

| Ladder diagram                                                                    | Structured text |

| Not supported. |

### Processing details

- These instructions indicate an end of a subroutine program.
- When the RET instruction is executed, the program execution returns to the step following the CALL(P) or XCALL instruction that called the subroutine program.

A: Main routine program  
B: Subroutine program

### Precautions

- If the RET (SRET) instruction is executed in a user interrupt program (I-IRET), a compiling error occurs.

### Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# Calling a subroutine program

## XCALL

FX5S

FX5UJ

FX5U

FX5UC

This instruction executes CALL for (turns on and executes) the subroutine program specified by (P) when the execution condition is established. When the condition is turned off, this instruction executes turns off and terminates for the subroutine program.

| Ladder diagram                                                                    | Structured text |

## Processing details

- The XCALL instruction controls the execution and non-execution processing of subroutine programs.
  - In the execution of subroutine programs, each coil instruction is operated according to the ON/OFF status of the condition contact.
  - In the non-execution processing of subroutine programs, each coil instruction is operated with the OFF status of the condition contact applied.
- The following table lists the operation result of each coil instruction after the non-execution processing. Regardless of the status of the condition contact, the following result is applied.

| Device used for operation                                                    | Operation result (device status)          |
|------------------------------------------------------------------------------|-------------------------------------------|
| 1 ms timer, 10 ms timer, 100 ms timer                                        | 0                                         |
| 1 ms retentive timer, 10 ms retentive timer, 100 ms retentive timer, counter | The current status is held.               |
| Device in the OUT instruction                                                | Forcibly turned off.                      |
| Device in the SET, RST, or SFT(P) instruction or basic/applied instruction   | The current status is held.               |
| PLS instruction, pulse instruction (□P)                                      | Same as when the condition contact is off |

- The following shows the operation of the XCALL instruction.

- (1) Rising edge of X0 (OFF → ON): The subroutine program of P1 is executed.
- (2) While X0 is on: The subroutine program of P1 is executed. (The rising edge of X0 is not included.)
- (3) Falling edge of X0 (ON → OFF): The non-execution processing of the subroutine program of P1 is executed.

- The XCALL instruction can be nested up to 16 levels. However, the 16 levels are the total of the CALL(P) and XCALL instructions.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 3360H                      | The 17th level of the nesting is executed.                                                                                             |
| 3380H                      | The subroutine program specified by the pointer in the XCALL instruction does not exist.                                               |
| 3381H                      | After the XCALL instruction is executed, the END, FEND, GOEND, or STOP instruction is executed before the RET instruction is executed. |
| 3382H                      | The RET (SRET) instruction is executed before the XCALL instruction is executed.                                                       |

## 8.5 Data Table Operation Instruction

### Reading the oldest data from the data table

#### SFRD(P)

**FX5S****FX5UJ****FX5U****FX5UC**

These instructions read data for first-in first-out control.

| Ladder diagram                                                                    | Structured text                               |

| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions transfer (read) (s)+1, which was sequentially written by the SFWR instruction, to (d), and shift the word data of (n)-1 points starting from (s)+1 upward by 1 word. Then, these instructions decrease the number of data points stored in (s) by 1.

- The data of (s)+1 is transferred (read) to (d). Accompanied by this transfer, the contents of the pointer (s) decrease, and the data is shifted upward by 1 word. (When the continuous operation type SFRD instruction is used, the contents are stored in turn in each operation cycle. Use the pulse operation type SFRDP instruction in programming.)

## Precautions

- The contents of (s)+(n) do not change by reading.
- When the continuous operation type (SFRD) instruction is used, data is read in turn in each scan time (operation cycle), but the contents of (s)+(n) do not change.
- When 0 is set in the pointer (s), no processing is executed and the contents of (d) do not change.

## Program example

## Operation error

| Error code (SD0/SD8067) | Description                                                                                                            |

## Processing details

- Every time the instruction is executed for the word devices (s) to (s)+(n)-1, a device "(s) + Pointer data (s)" is read to (d).  
(The last data entry written by the shift write (SFWR) instruction for first-in first-out control is read to (d).) Specify any value between 2 and 32767 for (n).
- Subtract "1" from the value of the pointer data (s).

Data for FILO control

|           | Description                                                            |
|-----------|------------------------------------------------------------------------|
| (s)       | Pointer data (amount of data stored)                                   |
| (s)+1     | Data area<br>(First-in data written by shift write (SFWR) instruction) |
| (s)+2     |                                                                        |
| (s)+3     |                                                                        |
| ⋮         |                                                                        |
| (s)+(n)-3 |                                                                        |
| (s)+(n)-2 |                                                                        |
| (s)+(n)-1 |                                                                        |

## Precautions

- If programed in the continuous operation type, the POP(P) instructions are executed in every operation cycle. As a result, expected operation may not be achieved. Usually, program the POP(P) instructions in the "pulse operation type", or let them be executed by a "pulsed command contact".
- When the current value of the pointer (s) is "0", the zero flag SM8020 turns ON and the POP(P) instructions are not executed.
- When the current value of the pointer (s) is "1", "0" is written to (s) and the zero flag SM8020 turns ON.

## Program example

Among values stored in D20 input first to D101 to D106, the last value input is stored to D10, and "1" is subtracted from the number of stored data (pointer D100) every time X0 turns ON.

When the first-in data is as shown in the table below

| Pointer | Data  |       |       |       |       |       |
|---------|-------|-------|-------|-------|-------|-------|
| D100    | D101  | D102  | D103  | D104  | D105  | D106  |
| K3      | H1234 | H5678 | HABCD | H0000 | H0000 | H0000 |

## Operation error

| Error code (SD0/SD8067) | Description                                                      |
|-------------------------|------------------------------------------------------------------|
| 2820H                   | The device range (s)+(n)-1 exceeds the device.                   |
| 3405H                   | (s) is larger than (n)-1.                                        |
|                         | (s) is smaller than 0.                                           |

## Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                                                                             | Range      | Data type              | Data type (label) |
|---------|-------------------------------------------------------------------------------------------------------------------------|------------|------------------------|-------------------|
| (s)     | Word device number storing data to be put in first                                                                      | —          | 16-bit signed binary   | ANY16             |
| (d)     | Start word device number storing and shifting data<br>(The start is a pointer. The data is stored starting from (d)+1.) | —          | 16-bit signed binary   | ANY16             |
| (n)     | Number of stored points plus "1".                                                                                       | 2 to 32768 | 16-bit unsigned binary | ANY16_U           |
| EN      | Execution condition                                                                                                     | —          | Bit                    | BOOL              |
| ENO     | Execution result                                                                                                        | —          | Bit                    | BOOL              |

### ■Applicable devices

| Operand | Bit                         | Word                      |       |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|-----------------------------|---------------------------|-------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, S | T, ST, C, D, W, SD, SW, R | U□\G□ | Z | LC          | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                           | ○                         | ○     | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- The contents of (s) are written to "(n)-1" devices from (d)+1, and "1" is added to the number of data stored in (d). For example, for (d)=0, the contents are written to (d)+1, and for (d)=1, to (d)+2.

- At the first execution, the contents of (s) are stored in (d)+1.
- When the contents of (s) are changed and then the instruction is executed again, the new contents of (s) are stored to (d)+2. So the contents of +2 become equivalent to (s). (When the continuous operation type SFWR instruction is used, the contents are stored in each operation cycle. Use the pulse operation type SFWRP instruction in programming.) Data is stored from the right end in the same way, and the number of stored data is specified by the contents of the pointer (d).

## Precautions

- In the case of the continuous operation type instruction (SFWR), note that data is stored (overwritten) in every scan time (operation cycle).

## Program example

For a program example, refer to [Page 468](#) Reading the oldest data from the data table.

## Operation error

### Processing details

- These instructions insert 16-bit binary data specified by (s) to the data table specified by (d) as the (n)th data. After these instructions are executed, the data after the (n)th data in the data table is moved down by one data point.

## Precautions

- The device range used in a data table should be controlled by the user.
- The data table has (d) number of stored data starting from ((d)+1).

## Program example

In the program shown below, data stored in D100 is inserted into the 3rd position of the data table stored in D0 to D4 when X10 is set to ON.

However, when the amount of data stored exceeds "7", the FINSP instruction is not executed.

(The device range used in the data table is D0 to D7).

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H                      | When the FINS(P) instructions are executed, the data table range exceeds the corresponding device range.                                      |
| 3405H                      | When the FINS(P) instructions are executed, the value (n) exceeds the corresponding device range of the table (d).                            |
|                            | When the FINS(P) instructions are executed, the table position (n) where the data is inserted exceeds "the number of stored data points + 1". |
|                            | The value set in (n) is other than the following.<br>2≤(n)≤32767                                                                              |

# Deleting data from the data table

## FDEL(P)

FX5S    FX5UJ    FX5U    FX5UC

These instructions remove the (n)th data in the data table specified by (d) and store the data in the device specified by (s). After these instructions are executed, the data after the (n)+1th data in the data table is moved up by one data point.

|                         | When the FDEL(P) instructions are executed, the table position (n) where the data to be deleted is stored exceeds the number of stored data points. |
|                         | The value set in (n) is other than the following.<br>2≤(n)≤32767                                                                                    |

## 8.6 Reading/writing Data Instructions

---

### Reading/Writing data to data memory

The data write instruction is an instruction to write arbitrary device data to data memory.

Writing the fixed values used for operation and operation results to data memory can prevent data loss when the battery is low.

The data that has been written to data memory can be read at any time using the data memory read instruction.

#### ■Execution method

Use the SP.DEVST instruction to write device data to data memory.

Use the S(P).DEVLD instruction to read device data from data memory to any specified device.

# Reading data from the data memory

## S(P).DEVLD

FX5S

FX5UJ

FX5U

FX5UC

Reads data from the device data storage file in data memory.

\*1 S cannot be used.

## Processing details

- These instructions read device data by the number of points specified by (n) from the read offset specified by (s) in the device data storage file in data memory, and store it in the device specified by (d). (s) indicates the offset from the start of the device data storage file and can be specified by word offsets (incremented by 1 every 16 bits).

- Use the SP.DEVST instruction to write device data to the device data storage file. (📖 Page 483 SP.DEVST)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                    |

<sup>\*1</sup> S cannot be used.

<sup>\*2</sup> T, ST, and C cannot be used.

## Processing details

- These instructions retrieve the specified number of points of data specified by (n) from the device specified by (s2) and write it to the write offset in the device specified by (s1) in the device data storage file in data memory. (s1) indicates the offset from the start of the device data storage file and can be specified by word offsets (incremented by 1 every 16 bits).

- The completion device specified by (d) automatically turns on upon execution of the END instruction following the detection of processing completion of the SP.DEVST instruction and turns off upon execution of the END instruction in the next scan, so it is used as the execution complete flag of the SP.DEVST instruction.
- If the SP.DEVST instruction completes with an error, the error completion device specified by (d)+1 turns on or off at the same time as the completion device specified by (d). Therefore, the device is used as the error completion flag of the SP.DEVST instruction.
- SM753 (File being accessed) turns on while the SP.DEVST instruction is executed. If SM753 has already been on, the SP.DEVST instruction cannot be executed. (If executed, no processing is performed.)
- If an error is detected during execution of the SP.DEVST instruction, the completion device (d), error completion device (d)+1, and SM753 do not turn on.
- Use the S(P).DEVLD instruction to read device data from the device data storage file to any specified device. (Page 481 S(P).DEVLD)

## Precautions

- The value written to data memory is the one at execution of the SP.DEVST instruction.
- Execution of the SP.DEVST instruction increases SD634 and SD635. The number of writes to the data memory of the CPU module is limited. If the data memory write count index exceeds twenty thousands, an error occurs with error code 1080H.
- To prevent the data memory write count from being increased by careless instruction execution, SD771 can be set to limit the write count per day. The maximum number of writes is 8 by default. Change the maximum number of writes by using SD771 as needed. If the specified write count is exceeded, an error occurs with error code 3421H. The number of executions of the instruction to write to data memory per day is initialized to 0 at the following timing.
  - When power off→on, or when reset→reset canceled.
  - The date (year, month, day) in clock data is changed by time advancement.
  - CPU module internal clock data (year, month, day) is changed by the clock data change function.
- Data is written to the device data storage file when the END instruction is executed. Data is written to the device data storage file when the END instruction is executed immediately after the SP.DEVST instruction is executed. Thus, depending on the number of write points, writing to the device data storage file may involve multiple scans. Check the completion device to see whether the writing is completed.
- When executing SP.DEVST instruction during backup by the backup restore function, the writing is completed abnormally. Do not execute the SP.DEVST instruction during backup. Executing the SP.DEVST instruction after confirming that the backup executing flag (SM1350) is off is recommended.

\*1 Only drive 2 (for the SD memory card) can be set.

\*2 Specification with a label is not allowed.

\*3 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

| +1 to +□      | Read data                    | The read data is stored.                                                                                     | —             | System |

### Processing details

- This instruction reads data from the specified file. Set the execution/completion type in the control data to specify the file read-target format.
- The read target is the data in the SD memory card only.
- The processing completion bit device (d3) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FREAD instruction is detected. The bit device (d3) turns off at the execution of the END instruction in the next scan. If the processing completion bit device (d3) is ON, it will automatically turn OFF when the SP.FREAD instruction is executed.
- If the SP.FREAD instruction completes with an error, the error completion device (d3)+1 turns on or off in synchronization with (d3).
- SM753 (File being accessed) turns on while the SP.FREAD instruction is being executed. While SM753 is on, the SP.FREAD instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- If an error is detected during the execution of the instruction, Processing Complete (d3), Error Completion (d3)+1, and SM753 do not turn on.
- When "Odd number of bytes" is specified by (d1)+7, the read data is stored as shown below. (In the shaded area shown below, the data before execution of the instruction is kept.)

\*1 Up to 32767 points (when the file register (R) is used) when only devices are used.

\*2 Specify the number of read-target data in word units adding 1 to the number of odd byte data to be read.

## ■Timing chart

Below is shown the timing chart (flag updating timing) from the execution of the SP.FREAD instruction to the completion.

\*1 The complete flag is not turned ON when an error is detected during instruction execution.

## ■When reading binary data

- If the extension of the target file is omitted, the extension will be ".BIN".
- If the specified file does not exist, an error (8002H) occurs.
- If the position is specified exceeding the existing file size, 0 point of data is read and the processing completes successfully.

The following figure shows an example of reading binary data.

**Ex.**

Example of reading binary data (16-bit binary data)

## ■When reading data after converted to CSV format

- Elements in the CSV format file (cells in Excel<sup>®</sup>) are read by each row and stored in the device.
- If the extension of the target file is omitted, the extension will be ".CSV".
- If the specified file does not exist, an error (8002H) occurs.
- If the position is specified exceeding the existing file size, 0 point of data is read and the processing completes successfully.
- The number of data specified by (d1)+2 is read from the beginning of the file. If the last data in the file is read before reaching to the number specified, only the available number of data is read.
- When the number of columns is set to 0, the data are read by ignoring the rows (CR+LF, only CR, only LF) in the CSV format file.
- The character code of the specified file is read as a shift JIS code when the specified execution/completion type is decimal, hexadecimal or single-precision real number.
- The string data in the CSV file and the value stored in the device after it is read are determined by the execution/completion type.

|                                                                           |                            | Numeric values other than above                                                                                                                      | 0                                 | Filled with 0 since it cannot be converted.                                                                                                                                                                                                                                           |

#### Ex.

When "Reading data after converted to CSV format" (String (ASCII data)) is specified

[Data stored in CSV format]

PARTS.CSV

| No.     | , | Name   | , | Value1 | , | Value2 | CR | LF |
|---------|---|--------|---|--------|---|--------|----|----|
| AA_0001 | , | Prts_A | , | 100    | , | 200    | CR | LF |
| BB_0002 | , | Prts_B | , | 300    | , | 400    | CR | LF |

Enclosed values as shown to the left are read.

(Total of six elements, three columns from two lines of PARTS.CSV, are read.)

[Data to be loaded to the device]

- (1) Start device for storing the data that has been read
- (2) File name
- (3) Control data

[Control data]

|     |       |
|-----|-------|
| D10 | H0130 |
| D11 | H0000 |
| D12 | K6    |
| D13 | K100  |
| D14 | 2H    |
| D15 | 3H    |
| D16 | 3H    |
| D17 | K2    |

- D10: Execution/completion type
- D11: Completion status
- D12: Number of read-target data
- D13: Maximum number of read data
- D14, D15: File position
- D16: Number of columns
- D17: Data type specification

[Loaded data]

D99: Number of data actually read  
D100 to D103: String in the 1st column of the 2nd line  
D104 to D107: String in the 2nd column of the 2nd line  
D108, D109: String in the 3rd column of the 2nd line  
D110 to D113: String in the 1st column of the 3rd line  
D114 to D117: String in the 2nd column of the 3rd line  
D118, D119: String in the 3rd column of the 3rd line

When String (ASCII data) is specified, it is necessary to set the total size (in word units) for the maximum number of read data ((d1)+3).

Example: When a string with 100 100-character elements is read from a CSV file, the size is as shown below.

- (100 (character) + 2 (NULL)) × 100 (element) = 10200 byte = 5100 word

In the above case, an area for 5101 words must be secured for the file name (s2).

**Ex.**

When "Reading data after converted to CSV format" (Decimal (16-bit data)) is specified and the number of columns is set to 0

[Data created in Excel]

|   | A             | B   | C              |
|---|---------------|-----|----------------|
| 1 | Main/sub item |     | Measured value |
| 2 | Length        | 1   | 3              |
| 3 | Temperature   | -21 |                |
| 4 |               |     |                |

[Data saved in CSV format]

ABCD.CSV

|               |   |     |                |    |       |

[Loaded data]

- D99: Number of data actually read
- D100: Since "Main/sub item" is not a numerical value, the conversion data, 0, is stored.
- D101: Since " " is not a numerical value, the conversion data, 0, is stored.
- D102: Since "Measured value" is not a numerical value, the conversion data, 0, is stored.
- D103: Since "Excess" is not a numerical value, the conversion data, 0, is stored.
- D104: Since "Length" is not a numerical value, the conversion data, 0, is stored.
- D105: Since "Temperature" is not a numerical value, the conversion data, 0, is stored.
- D106: Since "-21" is a numerical value, it is converted to a binary value.

**Point**

This type of file in which the number of columns vary with individual rows cannot be created by Excel. It is created when the CSV file is modified by a user.

- When the specified number of columns is set to a value other than 0, a CSV format file is read as the table with the specified number of columns. The elements outside the specified number of columns are ignored.

#### Ex.

When "Reading data after converted to CSV format" (Decimal (16-bit data)) is specified and the number of columns is set to a value other than 0 ((d1)+6 is set to 2)

[Data created in Excel]

|   | A             | B   | C              |
|---|---------------|-----|----------------|
| 1 | Main/sub item |     | Measured value |
| 2 | Length        | 1   | 3              |
| 3 | Temperature   | -21 |                |
| 4 |               |     |                |

[Data saved in CSV format]  
ABCD.CSV

|               |   |     |                |    |       |
|---------------|---|-----|----------------|----|-------|
| Main/sub item | , | ,   | Measured value | CR | LF    |
| Length        | , | 1   | ,              | 3  | CR LF |
| Temperature   | , | -21 | ,              |    | CR LF |

(1)

[Data to be loaded to the device]

(1) Columns out of the specified range are ignored.

(2) Start device for storing the data that has been read

(3) File name

(4) Control data

[Control data]

|     |       |
|-----|-------|
| D10 | 0100H |
| D11 | -     |
| D12 | K6    |
| D13 | K0    |
| D14 | 0H    |
| D15 | 0H    |
| D16 | 2H    |
| D17 | K0    |

D10: Execution/completion type

D11: Completion status

D12: Number of read-target data

D13: Maximum number of read data

D14, D15: File position

D16: Number of columns

D17: Data type specification

[Loaded data]

D99: Number of data actually read

D100: Since "Main/sub item" is not a numerical value, the conversion data, 0, is stored.

D101: Since " " is not a numerical value, the conversion data, 0, is stored.

D102: Since "Length" is not a numerical value, the conversion data, 0, is stored.

D103: Since "1" is a numerical value, it is converted to a binary value.

D104: Since "Temperature" is not a numerical value, the conversion data, 0, is stored.

D105: Since "-21" is a numerical value, it is converted to a binary value.

- When the number of columns differs in each row, the elements outside the specified number of columns are ignored and 0 is added to the cells where no element exists.

**Ex.**

When the number of columns differs in each row

[Data saved in CSV format]  
ABCD.CSV

|               |    |     |                |    |        |    |    |
|---------------|----|-----|----------------|----|--------|----|----|
| Main/sub item | ,  |     | Measured value | ,  | Excess | CR | LF |
| Length        | CR | LF  |                |    |        |    |    |
| Temperature   | ,  | -21 | CR             | LF |        |    |    |

(1) Columns out of the specified range are ignored.

[Data to be read into devices]

- (2) Start device for storing the data that has been read
- (3) File name
- (4) Control data

[Control data]

|     |       |
|-----|-------|
| D10 | 0100H |
| D11 | -     |
| D12 | K6    |
| D13 | K0    |
| D14 | 0H    |
| D15 | 0H    |
| D16 | 2H    |
| D17 | K0    |

- D10: Execution/completion type
- D11: Completion status
- D12: Number of read-target data
- D13: Maximum number of read data
- D14, D15: File position
- D16: Number of columns
- D17: Data type specification

[Loaded data]

- D99: Number of data actually read
- D100: Since "Main/sub item" is not a numerical value, the conversion data, 0, is stored.
- D101: Since " " is not a numerical value, the conversion data, 0, is stored.
- D102: Since "Length" is not a numerical value, the conversion data, 0, is stored.
- D103: Since no element exists, the conversion data, 0, is added.
- D104: Since "Temperature" is not a numerical value, the conversion data, 0, is stored.
- D105: Since "-21" is a numerical value, it is converted to a binary value.

- When "Reading data after converted to CSV format" is specified, data can be divided and read.

[Specify the row to start reading]

- Execution/completion type: Reading data after converted to CSV format (Decimal (16-bit data))
- Number of read-target data: K6
- File position: 2H
- Number of columns specification: 4H
- Data type specification: Words
- Read start device: D0
- Number of data actually read: 6H

- (1) Starting row
- (2) Next starting position
- (3) Data in the device (loaded data)
- N: Number of data

### [Continuing from the last read position]

- Execution/completion type: Reading data after converted to CSV format (Decimal (16-bit data))
- Number of read-target data: K5
- File position: FFFFFFFFH (continuing from the position where the previous reading ends)
- Number of columns specification: 4H
- Data type specification: Words
- Read start device: D7
- Number of data actually read: 5H

(1) Starting row

(2) Next starting position

(3) Data in the device (loaded data)

N: Number of data

### Point

- When reading data from the position where the previous reading ends, specify the same values for "Execution/End type", "Number of columns", and "Data type specification". If not, data cannot be added correctly from the position where the previous reading ends.
- While reading data from the position where the previous reading ends, if the SP.FREAD instruction with different settings or the SP.FWRITE instruction is executed, data cannot be added correctly from the position where the previous reading ends.
- If another file is specified when data is read continuously from the last read position, the data cannot be normally read from the last read position.
- If data is read continuously from the last read position at the time of initial file reading (for example after the power is turned on the CPU module), the data will be read from the beginning of the file position.
- When reading data after converted to CSV format (string (ASCII data)) has been specified, if the number of read data exceeds the maximum number of read data, the file position will be initialized to the beginning of file even if the reading from the last read position is continued.

# Ex.

## When out-of-range value or string data is read

[Data to be read into devices]

(1): Start device for storing the data that has been read

• D100: Number of data actually read

• D101 to D120: Read data

(2): File name

• "sample.csv"

(3): Control data

[Control data]

|    |       |
|----|-------|
| D0 | 0100H |
| D1 | -     |
| D2 | K20   |
| D3 | K0    |
| D4 |       |
| D5 | K2    |
| D6 | K5    |
| D7 | K2    |

D0: Execution/completion type

D1: Completion status

D2: Number of read-target data

D3: Maximum number of read data

D4, D5: File position

D6: Number of columns

D7: Data type specification

[SD memory card]

sample.csv

|   | A      | B      | C     | D     | E        | F      |
|---|--------|--------|-------|-------|----------|--------|
| 1 | 1      | 2      | 3     | 4     | 5        | 6      |
| 2 | 1      | 2      | 3     | 4     | 5        | 6      |
| 3 | A      | B      | C     | D     | E        | F      |
| 4 | -32769 | -32768 | 65535 | 65536 | 32768    | -32769 |
| 5 | A      | B      | C     | D     | 1.11E+16 | F      |
| 6 | G      | H      | I     | J     | 2.21E+16 | L      |

The data in the five columns from the second row are transferred to D101 to D120.

[Loaded data]

■sample.csv 2nd line

■sample.csv 3rd line

0 is stored in D106 to D110 because all are strings.

■sample.csv 4th line

■sample.csv 5th line

0 is stored in D111 and D114 because -32769 and 65536 are out of the range. 0 is stored in D116 to D120 because all are strings or out of the range.

If values that cannot be expressed in word units in decimal (values out of the range of -32768 to 65535, strings, etc.) are set in the elements of the CSV file, all are converted to 0 and stored in the corresponding devices. Even if 0 is stored due to out-of-range values, they are included in the number of data actually read.

## Program example

An example of a program for reading binary data/CSV data from the SD memory card by using the SP.FREAD instruction is shown below.

### ■Reading binary data

When X0 is turned ON, 100 data starting from the 16th word from the beginning of the "sample.bin" file stored in the SD memory card are stored in D101 to D200.

[Program operation]

1. Control data is created during RUN.
2. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
3. The SP.FREAD instruction is executed.\*<sup>1</sup>
4. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*<sup>1</sup> The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                                                                                                                                        |

[Ladder program]

## [ST program]

```
//(1) Creation of control data for file read instruction
IF SM402 THEN
D0 := H0; //Execution/completion type (Control data start device)
D1 := H0; //Completion status
D2 := 100; //Number of read-target data
D4:UD := H10; //File position
D7 := 2; //Data type specification
END_IF;

//(2) Processing to start up the drive contact (X0)
IF LDP(TRUE, X0) THEN
//Checking that the file being accessed flag is OFF
IF (SM753 <> TRUE) THEN
SET(TRUE, M0); //Holds drive contact
RST(TRUE, M100); //Initialize instruction execution complete flag
RST(TRUE, M101); //Initialize instruction execution error complete flag
END_IF;
END_IF;

//(3) Execution of file read instruction
IF M0 THEN
//Checking that the memory card disable request is OFF
IF (SM606 <> TRUE) THEN
//EN = TRUE (Enable Input, always execute)
//U = U1 (Dummy)
//S1 = 2 (Drive specification, 2 fixed)
//S2 = "sample.bin"(Start device where the file name is stored)
//D1 = D0 (Start device where the control data is stored)
//D2 = D100 (Start device for storing the data that has been read)
//D3 = M100 (Bit device that turns on upon completion of the processing)
SP_FREAD(TRUE, U1, 2, "sample.bin", D0, D100, M100);
END_IF;
END_IF;

//(4) Checking the instruction execution complete flag
IF M100 THEN
SET((M101 <> TRUE), M150); //Holds instruction execution complete flag
SET(M101, M151); //Holds instruction execution error complete flag
RST(TRUE, M0); //Releasing the drive contact
END_IF;
```

[Execution result]

When the target binary data is read by using the program example, the results are as shown below.

[Read target (sample.bin)]

|            |                                                                         |

- (1) 100 words from 03E9 to 044C are described. In the program example, the data is read starting from the 16th word, and so 03E9 (boxed) is stored in D101.
- (2) In the program example, 100 words of data are read, and so the number of data actually read is stored in D100, and the read data are stored in D101 to D200.

\*1 Device/Buffer Memory Batch Monitor (hexadecimal display) of engineering tool

## ■Reading data after converted to CSV format

When X0 is turned ON, 20 words of data in the five columns in the second to fifth rows in the "sample.csv" file stored in the SD memory card are stored in D101 to D120.

[Program operation]

1. Control data is created during RUN.
2. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
3. The SP.FREAD instruction is executed.\*<sup>1</sup>
4. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*<sup>1</sup> The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

- (1) In the program example, five columns in each row from the second row are read, and so 1 (boxed) is stored in D101.
- (2) In the program example, 20 words of data are read, and so the number of data actually read is stored in D100, and the read data are stored in D101 to D120. For values/strings that cannot be read in the execution/completion type format, the stored device values of the read data are 0. Even if the device values are 0, they are included in the number of read data.

\*1 Device/Buffer Memory Batch Monitor (decimal display) of engineering tool

## Precautions

- The SP.FREAD instruction cannot be executed in user interrupt programs. An error (3582H) will occur.
- The SP.FREAD instruction cannot be executed while SM606 (Memory card disable request) is ON. When SM606 is turned ON during execution of the instruction, the program will terminate abnormally. (The data that has been read before SM606 is turned ON will be stored in the devices.)
- When reading multiple elements at reading data after converted to CSV format, secure devices sufficient for the total size of the elements in the read data area before executing the instruction. Since read data is stored from (d2)+1, the number of words required to be secured as (d2) is ((total number of words for each element) + 1) words.
- The files in the system folder (\$MELPRJ\$) cannot be handled by the SP.FREAD instruction. If an access to any file in the system folder (\$MELPRJ\$) is requested, a calculation error (3405H) will occur.
- If the storage device exceeds the end of the device range, an error (2820H) will occur.
- The SP.FREAD instruction cannot be executed simultaneously with the SP.DEVST instruction, the SP.FTPPUT instruction, and the SP.FTPGET.
- Do not disconnect the power or remove the SD memory card during execution of the SP.FREAD instruction. (The file may be damaged, or an error may occur.)

## Point

When 16-bit data (0000H, 0100H or 0120H) has been specified for Execution/completion type (d1)+0, the setting range of the number of read-target data (d1)+2 is as shown below.

- Up to 64512 points when only label is used.
- Up to 32767 points (when the file register (R) is used) when only device is used.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 3582H                      | The SP.FREAD instruction is executed in an interrupt program.                                                                                                                                                                                                                                                                                                                                                                                                          |

If the SP.FREAD instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 579 Error codes generated for file operation instructions

# Writing data to the specified file

## SP.FWRITE

FX5S

FX5UJ

FX5U

FX5UC

This instruction writes device data to the specified file in an SD memory card.

| +1 to +□      | Write data                   | The number of data to be requested to write is stored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 0000H to FFFFH | User   |

\*1 When "1: Even number of bytes" or "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), the setting range of (s3)+0 (Number of request write data) is 1 to 32767.

\*2 Even when "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), specify the number in units of words. Add one byte to the odd number of bytes to be written and set the number in (s3)+0 (Number of request write data).

## Processing details

- This instruction writes the specified number of data to the specified file. Set the execution/completion type in the control data to specify the file write-target format.
- The write target is the SD memory card only.
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FWRITE instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan. If the processing completion bit device (d2) is ON, it will automatically turn OFF when the SP.FWRITE instruction is executed.
- If the SP.FWRITE instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2).
- SM753 (File being accessed) turns on while the SP.FWRITE instruction is being executed. While SM753 is on, the SP.FWRITE instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- Even if an error is detected during the execution of the instruction, the bit devices (d2) and (d2)+1 and SM753 do not turn on.
- Specify data in (s3)+0, (d1)+4, (d1)+5, and (d1)+2 depending on the combination of (d1)+0 and (d1)+7.

\*1 If the specified file does not exist and the number of write target data is 0, a folder to up to the specified path will be created, and the program will terminate normally without creating a file.

If the specified file exists and the number of request write data is 0, the program will terminate normally with the number of actually written data to 0 point

\*2 To specify the number of request write data, add 1 byte to the number of odd byte data to be written, and specify the sum in word units.

\*3 The set value is from 00000000H to FFFFFFFEH (from the beginning of the file) or FFFFFFFFH (added to the end of the file).

■Timing chart

Below is shown the timing chart (flag updating timing) from the execution of the SP.FWRITE instruction to the completion.

\*1 The complete flag is not turned ON when an error is detected during instruction execution.

## ■Writing binary data

- If the extension of the target file is omitted, the extension will be ".BIN".
- If a file that does not exist is specified, it will be created and data will be saved to the beginning of the file. The newly created file has the archive attribute.
- When an existing file is specified, data will be saved to the beginning of the file. If the size of data exceeds the size of the existing area in the file during writing, the excess data is additionally stored.
- If the specified position exceeds the existing file size, 0 point of data is written and the processing completes successfully.
- If the media runs out of free space during additional saving of data, an error occurs. In this case, the successfully written and additionally saved data is kept in the written state, and the program will terminate abnormally after additionally saving only the part that can be additionally saved. (8002H is stored in (d1)+1.)
- In 16-bit binary data write mode, when the number of request write data and file position are specified, data is written as follows.

■Converting and writing data in CSV format

- If the extension is omitted, the extension will be ".CSV".
  - When an existing file is specified, the following occurs.
    - When a value specified by (d1)+4 and (d1)+5 is other than FFFFFFFFH, data is saved to the file after deleting all the existing data in the file.
    - When a value specified by (d1)+4 and (d1)+5 is FFFFFFFFH, data is added and saved to the end of the file.\*1
  - When an existing file has been specified and "Add converting the last line feed code of file to a comma" has been specified in (d1)+3.b0, the data will be saved after the last line feed code of the file is converted to a comma. However, the last character of the file is not a line feed code, the character will not be converted to a comma, and the data will be saved to the end of the file.
  - If a file that does not exist is specified, it will be created and data will be saved to the beginning of the file. The newly created file has the archive attribute.
  - If the media runs out of free space during additional saving of data, an error occurs. In this case, the successfully saved data is kept in the written state, and the program will terminate abnormally after additionally saving only the part that can be additionally saved. (8002H is stored in (d1)+1.)
  - When the number of columns is set to 0, data is read as a single-row data in a CSV format file.
- \*1 When "Added to the end of the file" has been specified in (d1)+3.b0, the data will be saved by starting a new line under the last line of the file.  
When "Add converting the last line feed code of file to a comma (write continuing the last line)" has been specified, the data will be saved continuing the last line of the file.

Ex.

The number of columns is set to 0 when writing data after conversion to the CSV format.

(1) Specified in units of words  
(2) Same as the number of write data if case of normal completion

- When the specified number of columns is set to a value other than 0, a CSV format file is stored as the table with the specified number of columns.

Ex.

The number of columns is set to a value other than 0 when writing data after conversion to the CSV format.

(1) Specified in units of words  
(2) Same as the number of write data if case of normal completion

- The following figure shows how data is added.

[Specify the file to which data will be written.] (Even if the file exists, it is deleted and re-created.)

- Execution/completion type: Writing data after converted to CSV format (Decimal (signed 16-bit data))
- Number of request write data: 6H
- File position: 00000000H (from the beginning of the file)
- Number of columns specification: 4H
- Data type specification: Words
- Write start device: D0

(1) Starting row

(2) Data in the device (write data)

N: Number of data

- When the number of request write data is 0, the processing varies depending on the existence of the specified file.

[When the specified file exists]

Since data is written to 0 point, the specified file will not be updated.

The program is finished normally.

[When the specified file does not exist]

The specified folder path will be created, and the processing will be terminated. When the folder exists, no processing will be performed.

The specified file will not be created.

[Added to the end of the file]

- Execution/completion type: Writing data after converted to CSV format (Decimal (signed 16-bit data))
- Number of request write data: 8H
- File position: FFFFFFFFH (added to the end of the file)
- Number of columns specification: 3H
- Data type specification: Words
- Write start device: D7

**Point**

- To justify the written data columns, set "Number of request write data" to an integral multiple of "Specified number of columns". If the setting is not an integral multiple, the lines will vary in the number of columns.
- When data is added to the end of a file, columns are shifted if "Number of columns" is changed from the previous writing.
- When "String (ASCII data)" has been specified for execution/completion type, set 00H (NULL) at the end of the string of one element. When the string has an even number of bytes, set 0000H (NULL for 2 bytes) for the next 1 word.
- When "String (ASCII data)" has been specified for execution/completion type, the maximum number of characters in 1 element is 1999. If the number of characters exceeds 1999 and 00H (NULL) is not stored, the 2000th and following characters will not be written, and the next element will be written.
- When "String (ASCII data)" has been specified for execution/completion type, up to 1023 elements can be written by executing the instruction once.

• The following figures show an example of specifying "String (ASCII data)" for the execution/completion type.

**Ex.**

Writing data after converted to CSV format (string (ASCII data))  
[Data to be written to a file]

- (1) Data to be written
- (2) File name
- (3) Control data

[Control data]

|     |       |
|-----|-------|
| D10 | H0130 |
| D11 | H0000 |
| D12 | -     |
| D13 | K0    |
| D14 | 0H    |
| D15 | 0H    |
| D16 | 0H    |
| D17 | K2    |

- D10: Execution/completion type: String (ASCII data)
- D11: Completion status
- D12: Number of data actually written
- D13: Application setting area
- D14, D15: File position
- D16: Number of columns
- D17: Data type specification

CPU module  
Data storage device

- D99: Number of request write data
- D100 to D102: String to be written to the 1st column of the 1st line
- D103, D104: String to be written to the 2nd column of the 1st line
- D105, D106: String to be written to the 3rd column of the 1st line

Data written to Excel

|   | A    | B   | C   | D |
|---|------|-----|-----|---|
| 1 | ABCD | 123 | 456 |   |
| 2 |      |     |     |   |

**Point**

- Set 00H (NULL) in the end of the string in an element. When the number of bytes of the string is even, set 0000H (two bytes of NULL) in the next one word.
- The maximum number of characters in one element is 1999. If this maximum number is exceeded and 00H (NULL) is not stored, characters of 2000th character and after are not written and the write processing shifts to the next element.
- A maximum of 1023 elements can be written in a single instruction execution.

- The following table lists values to set in (s3)+1 and later and data to be written in a CSV file when "0140H: Floating point real number (single-precision real number)" is set to (d1)+0.

| Execution/completion type ((d1)+0)                               | Value to set in the write data ((s3)+1 and later)                                                                    | Data to be written in a CSV file                                                                   |
|------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| 0140H: Floating point real number (single-precision real number) | Values within the range of: $-2^{128} < \text{data} \leq -2^{-126}$ ,<br>0,<br>$2^{-126} \leq \text{data} < 2^{128}$ | A value (0 to 7 digits in the decimal part) as given on the left is written in exponential format. |
|                                                                  | Values other than above                                                                                              | 0 is written. (Data cannot be converted.)                                                          |

- The following shows how the file size (total number of bytes) is calculated when a CSV format file is written to the SD memory card.

[Total number of bytes] = [Total number of bytes excluding the last row] + [Number of bytes of the last row]

([Number of bytes of each row] = [Number of columns\*<sup>1</sup>] + 1 + [total number of bytes of all data values per line]<sup>\*2</sup>)

- \*2 The specified number of columns applies to rows other than the last row. The number of columns of the last row is calculated as shown below because it may differ from the specified number of rows depending on the number of write data.

· The number of rows excluding the last row is calculated. (Number of rows excluding the last row = number of requested write data ÷ number of columns (remainders rounded down))

· The number of columns of the last row is calculated. (Number of columns of the last row = number of requested write data - (number of rows excluding the last row × number of columns))

- \*3 The following shows how the number of bytes of each data value is calculated.

| Sign of data value | Number of bytes of each data value | Range of bytes                                             | Example                             |
|--------------------|------------------------------------|------------------------------------------------------------|-------------------------------------|
| Positive           | Number of digits                   | 1 to 5 (word specification)<br>1 to 3 (byte specification) | • 12345: 5 bytes<br>• 67: 2 bytes   |
| Negative           | Number of digits + 1               | 2 to 6 (word specification)<br>2 to 4 (byte specification) | • -12345: 6 bytes<br>• -67: 3 bytes |

## Program example

An example of a program for writing binary data/CSV data to the SD memory card by using the SP.FWRITE instruction is shown below.

### ■Writing binary data

When X0 is turned ON, the data in D101 to D200 are written starting from the 16th word from the beginning of the "sample.bin" file stored in the SD memory card.

[Program operation]

1. Control data is created during RUN.
2. Set the number of request write data.\*1
3. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
4. The SP.FWRITE instruction is executed.\*2
5. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*1 The data to be written must have been set although this step is not contained in the program example.

\*2 The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                                                                                                                                      |

| (d2)    | Bit device that turns on upon completion of the processing | M100: Execution complete flag<br>M101: Execution error completion flag                                                                                                                      |

## [ST program]

```
//(1) Creation of control data for file write instruction
IF SM402 THEN
D0 := H0; //Execution/completion type (Control data start device)
D1 := H0; //Completion status
D2 := 0; //Number of data actually written
D4:UD := H10; //File position
D7 := 2; //Data type specification
END_IF;

//(2) Creation of data to be written
IF SM402 THEN
D100 := 100; //Number of request write data
//Store the data to be written in D101 and following devices as needed.
END_IF;

//(3) Processing to start up the drive contact (X0)
IF LDP(TRUE, X0) THEN
//Checking that the file being accessed flag is OFF
IF (SM753 <> TRUE) THEN
SET(TRUE, M0); //Holds drive contact
RST(TRUE, M100); //Initialize instruction execution complete flag
RST(TRUE, M101); //Initialize instruction execution error complete flag
END_IF;
END_IF;

//(4) Execution of file write instruction
IF M0 THEN
//Checking that the memory card disable request is OFF
IF (SM606 <> TRUE) THEN
//EN = TRUE (Enable Input, always execute)
//U = U1 (Dummy)
//S1 = 2 (Drive specification, 2 fixed)
//S2 = "sample.bin" (Start device where the file name is stored)
//S3 = D100(Head device where the write-target data is stored)
//D1 = D0 (Start device where the control data is stored)
//D2 = M100 (Bit device that turns on upon completion of the processing)
SP_FWRITE(TRUE, U1, 2, "sample.bin", D100, D0, M100);
END_IF;
END_IF;

//(5) Checking the instruction execution complete flag
IF M100 THEN
SET((M101 <> TRUE), M150); //Holds instruction execution complete flag
SET(M101, M151); //Holds instruction execution error complete flag
RST(TRUE, M0); //Releasing the drive contact
END_IF;
```

## [Execution result]

When the target device data is written by using the program example, the results are as shown below.

[Write target]\*1

| Device Name | F | E | D | C | B | A | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | Current Value | String |
|-------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---------------|--------|

(2)

- (1) In the program example, 100 words of data are written. Accordingly, the number of request write data is stored in D100, and the data to be written are stored in D101 to D200.
- (2) 100 words from 03E9 to 044C (D101 to D200) are written. In the program example, the data is written starting from the 16th word, and therefore 03E9 (device value of D101) is stored in the 16th word.

\*1 Device/Buffer Memory Batch Monitor (hexadecimal display) of engineering tool

## ■Converting and writing data in CSV format

When X0 is turned on, the data in D101 to D115 are written to the end of the "sample.csv" file stored in the SD memory card.  
[Program operation]

1. Control data is created during RUN.
2. Set the number of request write data.\*1
3. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
4. The SP.FWRITE instruction is executed.\*2
5. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*1 The data to be written must have been set although this step is not contained in the program example.

\*2 The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                                                                                                                                                                                                                     |

[Write result (sample.csv)]

|   | A    | B    | C     | D      | E      | F   |
|---|------|------|-------|--------|--------|-----|
| 1 | 1    | 2    | 3     | 4      | 5      | 6   |
| 2 | 1    | 2    | 3     | 4      | 5      | 6   |
| 3 | A    | B    | C     | D      | E      | F   |
| 4 | 1    | 15   | 16    | 255    | 256    |     |
| 5 | 4095 | 4096 | 32767 | -32768 | -32767 | (2) |
| 6 | -1   | 0    | 4369  | 21845  | -21846 |     |
| 7 |      |      |       |        |        |     |

- (1) In the program example, 15 words of data are written. Accordingly, the number of request write data is stored in D100, and the data to be written are stored in D101 to D115.
- (2) The 15 words from 1 to -21846 (D101 to D115) are written. In the program example, the data are written by 5 columns to the end of the file, and therefore the data are stored after the existing data (that exists before writing).

\*1 Device/Buffer Memory Batch Monitor (decimal display) of engineering tool

## Precautions

- The SP.FWRITE instruction cannot be executed in user interrupt programs. An error (3582H) will occur.
- When "01\*\*H" has been specified in Execution/completion type (d1)+0 and an option other than "FFFFFFFFH" has been specified in File position (d1)+4 and (d1)+5, if "Add converting the last line feed code of file to a comma (write continuing the last line)" is specified in (d1)+3.b0, an error will occur.
- The SP.FWRITE instruction cannot be executed while SM606 (Memory card disable request) is ON. When SM606 is turned ON during execution of the instruction, the program will terminate abnormally. (The data that has been written before SM606 is turned ON will be stored in the SD memory card.)
- The files in the system folder (\$MELPRJ\$) cannot be handled by the SP.FWRITE instruction. If an access to any file in the system folder (\$MELPRJ\$) is requested, a calculation error (3405H) will occur.
- The SP.FWRITE instruction cannot be executed simultaneously with the SP.DEVST instruction, the SP.FTPPUT instruction, and the SP.FTPGET.
- Do not disconnect the power or remove the SD memory card during execution of the SP.FWRITE instruction. (The file may be damaged, or an error may occur.)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If the SP.FWRITE instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 579 Error codes generated for file operation instructions

# Deleting the specified file

## SP.FDELETE

FX5S

FX5UJ

FX5U

FX5UC

This instruction deletes the specified file or folder in an SD memory card.

| Ladder | ST                                 |
|--------|------------------------------------|
|        | ENO:=SP_FDELETE(EN,U,s1,s2,d1,d2); |

## Processing details

- This instruction deletes the file or folder specified by (s2) in the drive specified by (s1).
- SM753 (File being accessed) turns on while the SP.FDELETE instruction is being executed. While SM753 is on, the SP.FDELETE instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FDELETE instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan. If the processing completion bit device (d2) is ON, it will automatically turn OFF when the SP.FDELETE instruction is executed.
- If the SP.FDELETE instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2).
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

### Timing chart

The operation specifications of the file delete function are shown below.

| Application setting area (d1)+0 | File name/folder name (s2)                                                                |
|---------------------------------|-------------------------------------------------------------------------------------------|
| 0H, 1H, 3H                      | [When a file is specified]<br>sample/sample.bin<br>[When a folder is specified]<br>sample |

[In SD memory card]

■When application setting area is 0H (File)

■When application setting area is 1H ("Folder" + "Delete the folder even when it contains data.")

■When application setting area is 3H ("Folder" + "Delete the folder only when it is empty.")

\*1 The file or folder is deleted.

Below is shown the timing chart (flag updating timing) from the execution of the SP.FDELETE instruction to the completion.

\*2 The complete flag is not turned ON when an error is detected during instruction execution.

## Program example

When X0 is turned ON, the "\sample\sample.csv" file stored in the SD memory card is deleted.

[Program operation]

1. Control data is created during RUN.
2. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
3. The SP.FDELETE instruction is executed.\*1
4. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*1 The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X0     | Trigger of drive SP.FDELETE instruction                                                                                                                         |

[Ladder program]

## [ST program]

```
//(1) Creation of file delete instruction control data
IF SM402 THEN
D0:=H0; //Application setting area (File)
D1:=H0; //Completion status
END_IF;

//(2) Processing to start up the drive contact (X0)
IF LDP(TRUE,X0) THEN;
//Checking that the file being accessed flag is OFF
IF (SM753 <> TRUE) THEN
SET(TRUE,M0); //Holds drive contact
RST(TRUE,M100); //Initialize instruction execution complete flag
RST(TRUE,M101); //Initialize instruction execution error complete flag
END_IF;
END_IF;

//(3) Execution of file delete instruction
IF M0 THEN
//Checking that the memory card disable request is OFF
IF (SM606 <> TRUE) THEN;
//EN = TRUE (Enable Input, always execute)
//U = U1 (Dummy)
//S1 = 2 (Drive specification, 2 fixed)
//S2 = "\sample\sample.csv" (Start device where the file name is stored)
//D1 = D0 (Start device where the control data is stored)
//D2 = M100 (Bit device that turns on upon completion of the processing)
SP_FDELETE(TRUE, U1, 2, "\sample\sample.csv", D0, M100);
END_IF;
END_IF;

//(4) Checking the instruction execution complete flag
IF M100 THEN
SET((M101 <> TRUE), M150); //Holds instruction execution complete flag
SET(M101, M151); //Holds instruction execution error complete flag
RST(TRUE, M0); //Releasing the drive contact
END_IF;
```

## Precautions

- The SP.FDELETE instruction cannot be performed in user interrupt programs. An error (3582H) will occur.
- The SP.FDELETE instruction cannot be executed while SM606 (Memory card disable request) is ON. If SM606 is turned ON after the instruction is executed, the program will terminate abnormally. (The data deleted before SM606 is turned ON will not be restored.)
- The SP.FDELETE instruction specifying the system folder (\$MELPRJ\$) or a file in the system folder cannot be executed. If the SP.FDELETE instruction is executed, a calculation error (3405H) will occur.
- Even though the operating status of the CPU module is switched from RUN to STOP during instruction execution, the CPU module continues the processing of the instruction.
- If the instruction is completed with an error during processing, the file or folder already deleted is not restored.
- When the size of a file to be deleted or the number of files to be deleted becomes larger, the instruction will take more time to complete.
- Do not access the file being processed by the SP.FDELETE instruction from other functions. (The file may be corrupt or an error may occur.)
- Do not operate files or folders being accessed from other functions.
- The SP.FDELETE instruction cannot be executed simultaneously with the SP.DEVST instruction, the SP.FTPPUT instruction, and the SP.FTPGET.
- When the application setting area of the SP.FDELETE instruction is 1H ("Folder" + "Delete the folder even when it contains data"), if the folder specified in (s2) contains a folder whose path exceeds 244 characters or a file exceeding 253 characters, the 8006H error will occur.
- When the application setting area of the SP.FDELETE instruction is 3H ("Folder" + "Delete the folder only when it is empty"), if the folder specified in (s2) contains any file or folder, the 8004H error will occur.
- Do not disconnect the power or remove the SD memory card during execution of the SP.FDELETE instruction. (The file may be damaged, or an error may occur.)

If the SP.FDELETE instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 579 Error codes generated for file operation instructions

# Copying the specified file

## SP.FCOPY

**FX5S** **FX5UJ** **FX5U** **FX5UC**

This instruction copies the specified file or folder in an SD memory card. When a folder is specified, the specified folder is copied in its entirety, or all the files and subfolders in the specified folder are copied.

**Ladder**

### Processing details

- This instruction copies the file or folder specified by (s2) in the drive specified by (s1) to the folder specified by (s4) in the drive specified by (s3). When a folder is specified by (s2), a file and subfolder with the same names may exist in the copy destination. In this case, the instruction is not completed with an error even if the value of bit 1 (overwrite setting) of (d1) is 0. (Copying is skipped.)
- If the folder specified by (s4) does not exist in the copy destination, the folder is created automatically.
- SM753 (File being accessed) turns on while the SP.FCOPY instruction is being executed. While SM753 is on, the SP.FCOPY instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FCOPY instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan. If the SP.FCOPY instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2). If the processing completion bit device (d2) is ON, it will automatically turn OFF when the SP.FCOPY instruction is executed.
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

### ■Timing chart

The operation specifications of the file copy function are shown below.

| Command input<br><div style="border: 1px solid black; padding: 2px; display: inline-block;">             SP.FCOPY   (U)   (d1)   (s1)   (s2)   (s3)   (s4)   (d2)           </div> |  |                                                                                    |  |  |                                   |  |  |  |

| 0H, 1H, 5H, 7H                                                                                                                                                                     |  | [When a file is specified]<br>user1.csv<br>[When a folder is specified]<br>folder1 |  |  | folder2                           |  |  |  |

[In SD memory card]

■When application setting area is 0H (File)

Before execution of instruction

After execution of instruction

The folder1/user1.csv file is copied into folder2.

■When application setting area is 1H ("Folder", "Copy the folder in its entirety.")

Before execution of instruction

After execution of instruction

The folder configuration of the copy source is copied into folder2.

■When application setting area is 5H ("Folder", "Copy all the files and subfolders in the folder.")

Before execution of instruction

After execution of instruction

Only the file in the copy source folder is copied into folder2.

■When application setting area is 5H ("Folder", "Copy all the files and subfolders in the folder.", "Do not overwrite the file or folder.")

Before execution of instruction

After execution of instruction

Since the copy destination contains a file with the same name, the file is not copied. The SP.FCOPY instruction is completed normally.  
When the copy destination does not contain a file with the same name, the file is copied.

■When application setting area is 7H ("Folder", "Copy all the files and subfolders in the folder.", "Overwrite the file or folder.")

Before execution of instruction

After execution of instruction

folder2/user1.csv is copied overwriting the folder1/user1.csv file.

\*1 Root folder

\*2 File name of the copy source

\*3 Copy destination folder

\*4 Folder name of the copy source

Below is shown the timing chart (flag updating timing) from the execution of the SP.FCOPY instruction to the completion.

\*5 The complete flag is not turned ON when an error is detected during instruction execution.

## Program example

When X0 is turned ON, the "sample.bin" file stored in the SD memory card is copied into the "sample1" folder.

[Program operation]

1. Control data is created during RUN.
2. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
3. The SP.FCOPY instruction is executed.\*<sup>1</sup>
4. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*<sup>1</sup> The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X0     | Trigger of drive SP.FCOPY instruction                                                                                                                           |
| D0     | Start device where the control data is stored <ul style="list-style-type: none"> <li>• D0: Application setting area</li> <li>• D1: Completion status</li> </ul> |
| M0     | SP.FCOPY instruction execution latched device                                                                                                                   |

SET(M101, M151); //Holds instruction execution error complete flag

RST(TRUE, M0); //Releasing the drive contact

END\_IF;

## Precautions

- Do not execute the SP.FCOPY instruction in an interrupt program. Doing so may cause malfunction of the module.
- The SP.FCOPY instruction cannot be executed while SM606 (Memory card disable request) is ON. If SM606 is turned ON after the completion of the initial END processing during execution of the instruction, the program will terminate abnormally upon detection of turning ON. (The data copied before SM606 is turned ON are copied.)
- The SP.FCOPY instruction specifying the system folder (\$MELPRJ\$) or a file in the system folder cannot be executed. If the SP.FCOPY instruction is executed, a calculation error (3405H) will occur.
- Even though the operating status of the CPU module is switched from RUN to STOP during instruction execution, the CPU module continues the processing of the instruction.
- Ensure that the number of characters in a folder path or in the total of a folder path and a file name after copying does not exceed its limit. (The file may be inaccessible or an error may occur.)
- If the instruction is completed with an error during processing, the file or folder may remain under processing.
- When the size of a file to be copied or the number of files to be copied becomes larger, the instruction will take more time to complete.
- Do not access the file being processed by the SP.FCOPY instruction from other functions. (The file may be corrupt or an error may occur.)
- Do not operate files or folders being accessed from other functions. (8001H is stored in (d1)+1.)
- The SP.FCOPY instruction cannot be executed simultaneously with the SP.DEVST instruction, the SP.FTPPUT instruction, and the SP.FTPGET.
- Do not disconnect the power or remove the SD memory card during execution of the SP.FCOPY instruction. (The file may be damaged, or an error may occur.)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                            | A system folder (\$MELPRJ\$) which is directly under the root folder is in the folder path specified by (s2) or (s4).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3582H                      | The SP.FCOPY instruction is executed in an interrupt program.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

If the SP.FCOPY instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 579 Error codes generated for file operation instructions

# Moving the specified file

## SP.FMOVE

FX5S

FX5UJ

FX5U

FX5UC

This instruction moves the specified file or folder in an SD memory card. When a folder is specified, the specified folder is moved in its entirety, or all the files and subfolders in the specified folder are moved.

### Processing details

- This instruction moves the file or folder specified by (s2) in the drive specified by (s1) to the folder specified by (s4) in the drive specified by (s3). When a folder has been specified in (s2) and a file or a folder having the same name exists in the destination, the program does not terminate abnormally even if the value of b1 (overwrite setting) of (d1) is 0. (The movement is skipped.)
- If the folder specified by (s4) does not exist in the destination, the folder is created automatically.
- SM753 (File being accessed) turns on while the SP.FMOVE instruction is being executed. While SM753 is on, the SP.FMOVE instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FMOVE instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan. If the SP.FMOVE instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2). If the processing completion bit device (d2) is ON, it will automatically turn OFF when the SP.FMOVE instruction is executed.
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

■Timing chart

The operation specifications of the file move function are shown below.

| Application setting area (d1)+0 | File name/folder name (s2)                                                         | Destination folder path (s4) |
|---------------------------------|------------------------------------------------------------------------------------|------------------------------|
| 0H, 1H, 5H, 7H                  | [When a file is specified]<br>user1.csv<br>[When a folder is specified]<br>folder1 | folder2                      |

[In SD memory card]

Before execution of instruction

After execution of instruction

The folder1/user1.csv file is moved into folder2.

■When application setting area is 1H ("Folder", "Move the folder in its entirety.")

Before execution of instruction

After execution of instruction

The folder configuration of the source is moved into folder2.

■When application setting area is 5H ("Folder", "Move all the files and subfolders in the folder.")

Before execution of instruction

After execution of instruction

Only the file in the source folder is moved into folder2.

■When application setting area is 5H ("Folder", "Move all the files and subfolders in the folder.", "Do not overwrite the file or folder.")

Before execution of instruction

After execution of instruction

The file is not moved because a file with the same name exists in the destination. The SP.FCOPY instruction is finished normally. When there is not a file with the same name in the destination, the file is moved.

■When application setting area is 7H ("Folder", "Move all the files and subfolders in the folder.", "Overwrite the file or folder.")

Before execution of instruction

After execution of instruction

folder2/user1.csv is moved overwriting the folder1/user1.csv file.

- \*1 Root folder
- \*2 Source file
- \*3 Destination folder
- \*4 Source folder

Below is shown the timing chart (flag updating timing) from the execution of the SP.FMOVE instruction to the completion.

<sup>\*5</sup> The complete flag is not turned ON when an error is detected during instruction execution.

## Program example

When X0 is turned ON, the "sample" folder stored in the SD memory card is moved to the "sample1" folder.

[Program operation]

1. Control data is created during RUN.
2. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
3. The SP.FMOVE instruction is executed.\*<sup>1</sup>
4. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*<sup>1</sup> The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X0     | Trigger of drive SP.FMOVE instruction                                                                                                                           |
| D0     | Start device where the control data is stored <ul style="list-style-type: none"> <li>• D0: Application setting area</li> <li>• D1: Completion status</li> </ul> |
| M0     | SP.FMOVE instruction execution latched device                                                                                                                   |
| M100   | SP.FMOVE instruction execution complete flag                                                                                                                    |
| M101   | SP.FMOVE instruction execution error completion flag                                                                                                            |
| M150   | Normal open indication device                                                                                                                                   |
| M151   | Open error indication device                                                                                                                                    |

| (s1)    | Source drive                                               | K2 (SD memory card)                                                    |
| (s2)    | Start device where the file name to move is stored         | "sample"                                                               |
| (s3)    | Destination drive                                          | K2 (SD memory card)                                                    |
| (s4)    | Device for storing the destination folder path             | "sample1"                                                              |
| (d2)    | Bit device that turns on upon completion of the processing | M100: Execution complete flag<br>M101: Execution error completion flag |

[Ladder program]

#### [ST program]

```
//(1) Creation of control data for file move instruction
IF SM402 THEN
D0:=H1; //Application setting area(Folder, move the folder in its entirety)
D1:=H0; //Completion status
END_IF;
```

```
//(2) Processing to start up the drive contact (X0)
IF LDP(TRUE,X0) THEN;
//Checking that the file being accessed flag is OFF
IF (SM753 <> TRUE) THEN
SET(TRUE,M0); //Holds drive contact
RST(TRUE,M100); //Initialize instruction execution complete flag
RST(TRUE,M101); //Initialize instruction execution error complete flag
END_IF;
END_IF;
```

```
//(3) Execution of file move instruction
IF M0 THEN
//Checking that the memory card disable request is OFF
IF (SM606 <> TRUE) THEN;
//EN = TRUE (Enable Input, always execute)
//U = U1 (Dummy)
//S1 = 2 (Drive specification, 2 fixed)
//S2 = "sample" (Start device where the file name to move is stored)
//S3 = 2 (Drive specification, 2 fixed)
//S4 = "sample1" (Device for storing the destination folder path)
//D1 = D0 (Start device where the control data is stored)
//D2 = M100 (Bit device that turns on upon completion of the processing)
SP_FMOVE(TRUE, U1, 2, "sample", 2, "sample1", D0, M100);
END_IF;
END_IF;
```

```
//(4) Checking the instruction execution complete flag
IF M100 THEN
SET((M101 <> TRUE), M150); //Holds instruction execution complete flag
SET(M101, M151); //Holds instruction execution error complete flag
RST(TRUE, M0); //Releasing the drive contact
END_IF;
```

## Precautions

- Do not execute the SP.FMOVE instruction in an interrupt program. Doing so may cause malfunction of the module.
- The SP.FMOVE instruction cannot be executed while SM606 (Memory card disable request) is ON. If SM606 is turned ON after the completion of the initial END processing during execution of the instruction, the program will terminate abnormally upon detection of turning ON.
- The SP.FMOVE instruction specifying the system folder (\$MELPRJ\$) or a file in the system folder cannot be executed.
- Even though the operating status of the CPU module is switched from RUN to STOP during instruction execution, the CPU module continues the processing of the instruction.
- Ensure that the number of characters in a folder path or in the total of a folder path and a file name after moving does not exceed its limit. (The file may be corrupt or an error may occur.)
- If overwriting occurs, the time to complete the instruction may be extended.
- When overwriting occurs, ensure a free space of the same size as the operation target file.
- If the instruction is completed with an error during processing, the file or folder may remain under processing.
- If the size of a file to be moved or the number of files to be moved becomes larger due to overwriting, the instruction will take more time to complete.
- Do not access the file being processed by the SP.FMOVE instruction from other functions. (The file may be inaccessible or an error may occur.)
- Do not operate files or folders being accessed from other functions.
- The SP.FMOVE instruction cannot be executed simultaneously with the SP.DEVST instruction, the SP.FTPPUT instruction, and the SP.FTPGET.
- Do not disconnect the power or remove the SD memory card during execution of the SP.FMOVE instruction. (The file may be damaged, or an error may occur.)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 3582H                      | The SP.FMOVE instruction is executed in an interrupt program.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

If the SP.FMOVE instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

### Processing details

- This instruction rename the file or folder specified by (s2) in the drive specified by (s1) to the file name or folder name specified by (s3). If the file name or folder name specified by (s3) already exists, the instruction is completed with an error.
- SM753 (File being accessed) turns on while the SP.FRENAME instruction is being executed. While SM753 is on, the SP.FRENAME instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FRENAME instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan. If the SP.FRENAME instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2). If the processing completion bit device (d2) is ON, it will automatically turn OFF when the SP.FRENAME instruction is executed.
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.
- If the file path + folder name and the folder path exceed the limit number of characters after renaming, the program is finished abnormally. (8006H is stored in (d1)+1.)

■Timing chart

The operation specifications of the file rename function are shown below.

Below is shown the timing chart (flag updating timing) from the execution of the SP.FRENAME instruction to the completion.

\*1 The complete flag is not turned ON when an error is detected during instruction execution.

## Program example

When X0 is turned ON, the file name of "sample.bin" stored in the SD memory card is changed to "sample\_change.bin".

[Program operation]

1. Control data is created during RUN.
2. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
3. The SP.FRENAME instruction is executed.\*<sup>1</sup>
4. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*<sup>1</sup> The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                     |

[Ladder program]

## Precautions

- Do not execute the SP.FRENAME instruction in an interrupt program. Doing so may cause malfunction of the module.
- The SP.FRENAME instruction cannot be executed while SM606 (Memory card disable request) is ON. When SM606 is turned ON during execution of the instruction, the program will terminate abnormally. (If the file renaming has been completed before SM606 is turned ON, the file name will be changed.)
- The SP.FRENAME instruction specifying the system folder (\$MELPRJ\$) or a file in the system folder cannot be executed.
- Even though the operating status of the CPU module is switched from RUN to STOP during instruction execution, the CPU module continues the processing of the instruction.
- Ensure that the number of characters in a folder path or in the total of a folder path and a file name after changing does not exceed its limit. (The file may be inaccessible or an error may occur.)
- Do not access the file being processed by the SP.FRENAME instruction from other functions. (The file may be corrupt or an error may occur.)
- Do not operate files or folders being accessed from other functions.
- The SP.FRENAME instruction cannot be executed simultaneously with the SP.DEVST instruction, the SP.FTPPUT instruction, and the SP.FTPGET.
- Do not disconnect the power or remove the SD memory card during execution of the SP.FRENAME instruction. (The file may be damaged, or an error may occur.)

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

\*1 When the bit device digit is specified in (d2), only multiples of 16 (0, 16, 32, 64...) can be specified as the device number. Only K4 can be specified as the number of digits.

\*2 S cannot be used.

\*3 T, ST, and C cannot be used.

Only bit specification of word device is applicable.

## ■Control data (d1)

| Operand: (d1) |                          |                                                                                                                                                                                                                                                                                                                                                                                      |                                    |        |

\*1 In the case of files/folders accessed in an environment (OS) other than the CPU module, the range of values to be acquired depends on the environment (OS).

### Processing details

- This function acquires the status of the file or folder specified by (s2) in the drive specified by (s1) and stores it in the device (d2) and after. When a folder is specified by (s2), 0 is stored in (d2)+2 to (d2)+3.
- SM753 (File being accessed) turns on while the SP.FSTATUS instruction is being executed. While SM753 is on, the SP.FSTATUS instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d3) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FSTATUS instruction is detected. The bit device (d3) turns off at the execution of the END instruction in the next scan. If the SP.FSTATUS instruction completes with an error, the error completion device (d3)+1 turns on or off in synchronization with (d3). If the processing completion bit device (d3) is ON, it will automatically turn OFF when the SP.FSTATUS instruction is executed.
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

■Timing chart

The operation specifications of the file status acquisition function are shown below.

Below is shown the timing chart (flag updating timing) from the execution of the SP.FSTATUS instruction to the completion.

\*1 The complete flag is not turned ON when an error is detected during instruction execution.

## Program example

When X0 is turned ON, the status of the "sample.bin" file stored in the SD memory card is read to D100 to D109.

[Program operation]

1. Control data is created during RUN.
2. The drive contact of X0 is held in M0. When the drive contact is turned ON, the instruction execution complete flag and instruction error completion flag are initialized.
3. The SP.FSTATUS instruction is executed.\*<sup>1</sup>
4. Since the instruction execution complete flag and instruction error completion flag are ON only during 1 scan, they are held in the M150 and M151 devices to identify the normal/abnormal completion.

\*<sup>1</sup> The instruction is executed after confirming that the following special devices are OFF to prevent simultaneous execution of another file operation instruction.

- SM606 (Memory card disable request)
- SM753 (File being accessed)

[Devices used]

| Device | Description                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X0     | Trigger of drive SP.FSTATUS instruction                                                                                                                         |

[Ladder program]

#### [ST program]

```

// (1) Creation of control data for file status acquisition instruction
IF SM402 THEN
  D0:=H0; //Application setting area (File)
  D1:=H0; //Completion status
END_IF;

// (2) Processing to start up the drive contact (X0)
IF LDP(TRUE,X0) THEN;
  //Checking that the file being accessed flag is OFF
  IF (SM753 <> TRUE) THEN
    SET(TRUE,M0); //Holds drive contact
    RST(TRUE,M100); //Initialize instruction execution complete flag
    RST(TRUE,M101); //Initialize instruction execution error complete flag
  END_IF;
END_IF;

// (3) Execution of file status acquisition instruction
IF M0 THEN
  //Checking that the memory card disable request is OFF
  IF (SM606 <> TRUE) THEN;
    //EN = TRUE (Enable Input, always execute)
    //U = U1 (Dummy)
    //S1 = 2 (Drive specification, 2 fixed)
    //S2 = "sample.bin" (Start device where the file name is stored)
    //D1 = D0 (Start device where the control data is stored)
    //D2 = D100 (Start device for storing the file status)
    //D3 = M100 (Bit device that turns on upon completion of the processing)
    SP_FSTATUS(TRUE, U1, 2, "sample.bin", D0, D100, M100);
  END_IF;
END_IF;

// (4) Checking the instruction execution complete flag
IF M100 THEN
  SET((M101 <> TRUE), M150); //Holds instruction execution complete flag
  SET(M101, M151); //Holds instruction execution error complete flag
  RST(TRUE, M0); //Releasing the drive contact
END_IF;
  
```

## Precautions

- Do not execute the SP.FSTATUS instruction in an interrupt program. Doing so may cause malfunction of the module.
- The SP.FSTATUS instruction cannot be executed while SM606 (Memory card disable request) is ON. When SM606 is turned ON during execution of the instruction, the program will terminate abnormally.
- The SP.FSTATUS instruction specifying the system folder (\$MELPRJ\$) or a file in the system folder cannot be executed.
- Even though the operating status of the CPU module is switched from RUN to STOP during instruction execution, the CPU module continues the processing of the instruction.
- The SP.FSTATUS instruction cannot be executed simultaneously with the SP.DEVST instruction, the SP.FTPPUT instruction, and the SP.FTPGET.
- Do not disconnect the power or remove the SD memory card during execution of the SP.FSTATUS instruction.

## Operation error

| Error code<br>(SD0/SD8067) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

If the SP.FSTATUS instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 579 Error codes generated for file operation instructions

## Error codes generated for file operation instructions

The following table lists the error codes that could be stored in the completion status of file operation instructions.

| Error code | Description                                                                                                                                                                                                                                    | Action                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8000H      | SM606 (SD memory card forced disable instruction) is on.                                                                                                                                                                                       | Turn off SM606 to cancel the SD memory card forced disable status.                                                                                                                                                                                                                                                                                                                                                                        |
|            | No SD memory card is inserted.                                                                                                                                                                                                                 | Insert an SD memory card.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|            | The SD memory card is not mounted.                                                                                                                                                                                                             | Mount the SD memory card.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 8001H      | An access to the SD memory card has failed.                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>• Check that the file name string are correctly specified.</li> <li>• Check that no other functions are accessing the file.</li> <li>• Take measures to reduce noise.</li> <li>• Reset the CPU module and run it again. If the same error code is displayed again, the possible cause is a hardware failure of the SD memory card. Please consult your local Mitsubishi representative.</li> </ul> |
|            | The SD memory card is write-protected.                                                                                                                                                                                                         | Unlock the write protect switch of the SD memory card.                                                                                                                                                                                                                                                                                                                                                                                    |
|            | The file is set for read only.                                                                                                                                                                                                                 | Clear the read-only setting.                                                                                                                                                                                                                                                                                                                                                                                                              |

## 8.8 Extended File Register Operation Instruction

### Reading extended file register

#### ERREAD

**FX5S****FX5UJ****FX5U****FX5UC**

Reads the current value of the extended file register (ER) to the file register (R) in the CPU built-in memory.

\*1 Only R can be used.

\*2 T, ST, and C cannot be used.

## Processing details

The current value of the extended file register (ER) stored into the SD memory card is read for (n) points to the file register (R) in the CPU built-in memory specified with (s).

The normal or abnormal completion of the ERREAD instruction can be confirmed with the instruction completion device (d) specified with the setting data.

- Instruction completion device (d)+0: Turns off when the ERREAD instruction is activated, and turns on during the instruction processing for the scan in which the ERREAD instruction has completed normally.
- Instruction completion device (d)+1: Turns off when the ERREAD instruction is activated, and turns on during the instruction processing for the scan in which the ERREAD instruction has completed abnormally.

Also, when the ERREAD instruction has completed normally/abnormally, instruction execution complete flag (SM8029) and instruction execution abnormal end flag (SM8329) turn on only for one scan at the same timing with the instruction completion device (d). After the contact of the ERREAD instruction turns on, the extended file register (ER) access flag (SM9366) turns on during access to the extended file register.

### Point

- When (s)=0 (R0), and (n)=0 (the number of read points: 0) are specified, all the points (32768 points) of the extended file register (ER) are read to the file register (R) in the CPU built-in memory in a batch.
- The following action takes place when (s) = 1 or more (from R1) and (n) = 0 (number of read points: 0) is set.
  - FX5S/FX5U/FX5UC CPU module: ER (s) to the range of assigned device points are read out to the file register (R) in the CPU built-in memory.
  - FX5UJ CPU module: ER (s) to ER32767 are read out to the file register (R) in the CPU built-in memory.
- Even if the command input of ERREAD instruction is set to OFF while the extended file register is being read, ERREAD instruction is executed until reading is completed.

## ■Related devices

| Device | Name                                    | Description                                            |
|--------|-----------------------------------------|--------------------------------------------------------|
| SM8029 | Instruction execution complete          | Turns on when an instruction is finished normally.     |
| SM8329 | Instruction execution abnormal end      | Turns on when an instruction is finished abnormally.   |
| SM9366 | Extended file register (ER) access flag | Turns on during access to extended file register (ER). |

### Point

SM8029 and SM8329 are the flags shared by multiple instructions. Program flag contacts directly under each instruction. For details, refer to  Page 45 Handling general flags.

## Precautions

- If the ERREAD instruction is executed, an access to the SD memory card occurs and the scan time is extended.
- This instruction cannot be executed with the extended file register operation instruction simultaneously.
- When executing the following extended file register operation instruction, detect the extended file register (ER) access flag: SM9366 switching from ON to OFF, and turn on the drive contact of the extended file register operation instruction.
- The ERREAD instruction cannot be executed in the interrupt program.
- Do not change the value of the file register (R) during transferring the extended file register (ER).
- Do not turn off the power supply of the CPU module during access to the extended file register (ER).

## Operation error

## Processing details

The current value of the file register (R) in the CPU built-in memory is written (transferred) for (n) points to the extended file register (ER) in the SD memory card specified with (s).

The normal or abnormal completion of the ERWRITE instruction can be confirmed with the instruction completion device (d) specified with the setting data.

- Instruction completion device (d)+0: Turns off when the ERWRITE instruction is activated, and turns on during the instruction processing for the scan in which the ERWRITE instruction has completed normally.
- Instruction completion device (d)+1: Turns off when the ERWRITE instruction is activated, and turns on during the instruction processing for the scan in which the ERWRITE instruction has completed abnormally.

Also, when the ERWRITE instruction has completed normally/abnormally, instruction execution complete flag (SM8029) and instruction execution abnormal end flag (SM8329) turn on only for one scan at the same timing with the instruction completion device (d). After the contact of the ERWRITE instruction turns on, the extended file register (ER) access flag (SM9366) turns on during access to the extended file register (ER).

### Point

- When (s)=0 (R0), and (n)=0 (the number of write points: 0) are specified, all the points (32768 points) of the file register (R) in the CPU built-in memory are written to the extended file register (ER) in a batch.
- The following action takes place when (s) = 1 or more (from R1) and (n) = 0 (number of write points: 0) is set.
  - FX5S/FX5U/FX5UC CPU module: R (s) to the range of assigned device points in the CPU built-in memory are written to the extended file register (ER).
  - FX5UJ CPU module: R (s) to R32767 in the CPU built-in memory are written to the extended file register (ER).
- Even if the command input of ERWRITE instruction is set to OFF while the extended file register is being written, ERWRITE instruction is executed until writing is completed.

## Processing details

Initializes all the points of the extended file register (ER) in the SD memory card in a batch.

The normal or abnormal completion of the ERINIT instruction can be confirmed with the instruction completion device (d) specified with the setting data.

- Instruction completion device (d)+0: Turns off when the ERINIT instruction is activated, and turns on during the instruction processing for the scan in which the ERINIT instruction has completed normally.
- Instruction completion device (d)+1: Turns off when the ERINIT instruction is activated, and turns on during the instruction processing for the scan in which the ERINIT instruction has completed abnormally.

Also, when the ERINIT instruction has completed normally/abnormally, instruction execution complete flag (SM8029) and instruction execution abnormal end flag (SM8329) turn on only for one scan at the same timing with the instruction completion device (d). After the contact of the ERINIT instruction turns on, the extended file register (ER) access flag (SM9366) turns on during access to the extended file register (ER).

### Point

- The initial value of the extended file register (ER) when initializing is 65535 (FFFFH).
- Even if the command input of ERINIT instruction is set to OFF while the extended file register is initialized in a batch, ERINIT instruction is executed until initialization is completed.

## Related devices

| Device | Name                                    | Description                                            |
|--------|-----------------------------------------|--------------------------------------------------------|
| SM8029 | Instruction execution complete          | Turns on when an instruction is finished normally.     |
| SM8329 | Instruction execution abnormal end      | Turns on when an instruction is finished abnormally.   |
| SM9366 | Extended file register (ER) access flag | Turns on during access to extended file register (ER). |
